

# INTRODUCTION TO SHIMURA VARIETIES

ANDREAS MIHATSCH

ABSTRACT. These are lecture notes for a course on Shimura varieties I am currently teaching at Zhejiang University. Comments are highly welcome and much appreciated.

## 1. INTRODUCTION

In this first lecture, we will learn, very roughly, what Shimura varieties are and why they are interesting. Everything brought up today will be covered in much more detail later in the course, and it will be perfectly normal that many terms will be new during a first reading. Our goal today is only to get an overview.

**1.1. Why study Shimura varieties?** Shimura varieties combine two interesting properties:

- They are varieties defined over number fields which makes them interesting from a number theory perspective. Most importantly, their étale cohomology groups are representations of Galois groups of number fields.
- Their definition is in terms of connected reductive algebraic groups  $G/\mathbb{Q}$ . They come equipped with an action of the adelic points  $G(\mathbb{A}_f)$ , which implies that their étale cohomology groups are also  $G(\mathbb{A}_f)$ -representations.

Hence, the étale cohomology groups of Shimura varieties are both Galois and  $G(\mathbb{A}_f)$ -representations. Conjecturally, this two-fold structure is described by the global Langlands correspondence. Conversely, one can use the cohomology of Shimura varieties to prove important cases of this correspondence. This is the main motivation for our course, and our overall aim is to learn about several important ideas in this context.

Let us mention that Shimura varieties are also interesting for other reasons. For example, the study of heights on the Siegel variety plays an important role in Faltings's proof of the Mordell Conjecture [3]. Another example is the Gross–Zagier formula [5], which states an identity between height pairings of complex multiplication points on the modular curve and derivatives of  $L$ -functions. It plays a major role in the proof of cases of the Birch–Swinnerton-Dyer Conjecture. Its higher-dimensional generalizations, the arithmetic

Gan–Gross–Prasad Conjectures [4, 17], are an important topic in current arithmetic geometry research. In a related direction, the Kudla program [8] seeks to establish connections between cycles on Shimura varieties and modular forms or Eisenstein series. The proof of the averaged Colmez conjecture [1, 16] has been an application of such ideas.

**1.2. This course.** The first part of our course will be an introduction to Shimura varieties. We will learn how to define them in terms of moduli spaces of abelian varieties and how to relate this definition to the group-theoretic one of Deligne. One of our goals is to obtain familiarity with the adelic formalism which will become important later.

In the second part of the course, we will study the cohomology of Shimura varieties. We will first get to know Matsushima’s formula, which expresses the Betti cohomology of compact Shimura varieties in terms of automorphic representations. We will then learn about point counting in characteristic  $p$  (Langlands–Kottwitz method). The aim here is to give an orbital integral expression for the number of  $\mathbb{F}_{p^n}$ -points of the reduction mod  $p$  of the Shimura variety.

**1.3. References.** The following two are our main background references.

- The introductory lecture notes by Milne [12]. They focus on the group-theoretic definition of Shimura varieties and the definition of canonical models.
- The first few articles in the lecture notes volume [6]. They provide an introduction to PEL type Shimura varieties. The article of Yihang Zhu [18] is directly related to the material of the second part of the course.

**1.4. Prerequisites.** We will assume as little as possible. The only necessary background is some familiarity with varieties and algebraic number theory.

In the rest of this introduction, we sketch the definition of Shimura varieties and give an outline of the course contents.

**1.5. Shimura data.** Shimura varieties are attached to Shimura data. The formalism starts with a connected reductive group  $G$  over  $\mathbb{Q}$ . For example,  $G$  might be one of the following.

- $G = \mathrm{GL}_2$
- $G = \mathrm{GSp}_{2g}$ , the general symplectic group in  $2g$  variables. Let  $J = \begin{pmatrix} & 1_g \\ -1_g & \end{pmatrix}$  be the matrix defining the standard symplectic form on  $\mathbb{Q}^{2g}$ . Then  $\mathrm{GSp}$  is defined by

$$\mathrm{GSp}_{2g}(\mathbb{Q}) = \{g \in \mathrm{GL}_{2g}(\mathbb{Q}) \mid {}^t g \cdot J \cdot g = c \cdot J \text{ for some } c \in \mathbb{Q}^\times\}. \quad (1.1)$$

It is related to the usual symplectic group  $\mathrm{Sp}_{2g}$  by the exact sequence

$$1 \longrightarrow \mathrm{Sp}_{2g} \longrightarrow \mathrm{GSp}_{2g} \xrightarrow{c} \mathrm{GL}_1 \longrightarrow 1.$$

The map  $c$  is called the *similitude factor*. Note that  $\mathrm{GSp}_2 = \mathrm{GL}_2$  and  $\mathrm{Sp}_2 = \mathrm{SL}_2$ , recovering the previous example.

- $G = \mathrm{U}(V)$ , a unitary group. Let  $K/\mathbb{Q}$  be an imaginary quadratic extension. (This means that  $\mathbb{R} \otimes_{\mathbb{Q}} K \cong \mathbb{C}$ .) Let  $V$  be an  $n$ -dimensional hermitian  $K$ -vector space. If  $V$  is not positive or negative definite then  $\mathrm{U}(V)$  can occur as part of a Shimura datum.

Next, the formalism requires the datum of a homomorphism of real algebraic groups

$$h : \mathbb{C}^\times \longrightarrow G(\mathbb{R}) \quad (1.2)$$

which satisfies certain axioms introduced by Deligne [2]. Such an  $h$  is called a *Deligne homomorphism*. If  $g \in G(\mathbb{R})$  is a real point of  $G$ , then we may conjugate  $h$  to define a new Deligne homomorphism,

$$(ghg^{-1})(z) := gh(z)g^{-1}.$$

Let  $S_h \subset G(\mathbb{R})$  denote the centralizer of  $h$ , meaning the subgroup of elements  $g$  with  $ghg^{-1} = h$ . The quotient  $X = G(\mathbb{R})/S_h$  is precisely the set of Deligne homomorphisms that are conjugate to  $h$ . An important consequence of Deligne's axioms is that  $X$  is a finite union of hermitian symmetric domains for  $G(\mathbb{R})$ . In particular, it is a complex manifold. The pair  $(G, X)$  is called a *Shimura datum*.

**Example 1.1.** Consider  $G = \mathrm{GL}_2$ . We can embed  $\mathbb{C}$  into  $M_2(\mathbb{R})$  as  $\mathbb{R}$ -algebra by

$$h(a + bi) := \begin{pmatrix} a & -b \\ b & a \end{pmatrix}.$$

If we restrict this embedding to unit groups, then we obtain a Deligne homomorphism  $h : \mathbb{C}^\times \rightarrow \mathrm{GL}_2(\mathbb{R})$ . Its centralizer is precisely  $h(\mathbb{C}^\times)$  and the quotient  $X$  is the set of complex structures on  $\mathbb{R}^2$ . Since  $\mathbb{C}^\times$  is connected and since  $\mathrm{GL}_2(\mathbb{R})$  has two connected components,  $X$  has two connected components. We want to give a more explicit description of  $X$ .

Recall that  $\mathbb{P}^1(\mathbb{C})$  is the space of complex lines in  $\mathbb{C}^2$ . Clearly, the Lie group  $\mathrm{GL}_2(\mathbb{C})$  acts on it by its natural action on  $\mathbb{C}^2$ . The subgroup  $\mathrm{GL}_2(\mathbb{R})$  preserves the real projective line  $\mathbb{P}^1(\mathbb{R})$  and hence acts on the complement,

$$\mathrm{GL}_2(\mathbb{R}) \curvearrowright \mathbb{C} \setminus \mathbb{R}, \quad g \cdot \tau = \frac{a\tau + b}{c\tau + d}. \quad (1.3)$$

The complement  $\mathbb{C} \setminus \mathbb{R}$  is the union of the upper and lower half plane which we often denote by  $\mathbb{H}^\pm$ . As an open subset of  $\mathbb{C}$ , it is naturally a complex manifold. Let us compute the stabilizer of  $i$ :

$$\begin{aligned} i = \frac{ai + b}{ci + d} &\iff -c + di = ai + b \\ &\iff a = d, \quad c = -b. \end{aligned} \quad (1.4)$$

That is, the stabilizer of  $i$  is precisely  $h(\mathbb{C}^\times)$ . Moreover, it is clear that  $\mathrm{GL}_2(\mathbb{R})$  acts transitively on  $\mathbb{H}^\pm$  because

$$\begin{pmatrix} a & b \\ 1 & 1 \end{pmatrix} \cdot i = ai + b.$$

Hence, we see that

$$X \xrightarrow{\sim} \mathbb{H}^\pm, \quad ghg^{-1} \mapsto g \cdot i \quad (1.5)$$

as smooth manifolds in a  $\mathrm{GL}_2(\mathbb{R})$ -equivariant way. We have not defined the complex structure on  $X$ , but it is, in fact, given by the complex structure on  $\mathbb{H}^\pm$  under (1.5).

**Remark 1.2.** Some groups, such as  $\mathrm{GL}_n$  with  $n \geq 3$ , cannot occur as part of a Shimura datum. For example, the dimension of the symmetric space for  $\mathrm{GL}_3(\mathbb{R})$  is

$$\dim \mathrm{SL}_3(\mathbb{R}) - \dim \mathrm{SO}(3) = 8 - 3$$

which is odd and hence cannot be a complex manifold.

**1.6. Shimura varieties over  $\mathbb{C}$ .** Given a Shimura datum  $(G, X)$ , one next defines a complex variety in the following way. Let  $\mathbb{A}$  denote the ring of adeles of  $\mathbb{Q}$ , and let  $\mathbb{A} = \mathbb{A}_f \times \mathbb{R}$  be its factorization into finite and archimedean part. (We will review these definitions later in the course.) Given an open compact subgroup  $K \subset G(\mathbb{A}_f)$ , the quotient  $G(\mathbb{A}_f)/K$  is a discrete countably infinite set with transitive  $G(\mathbb{A}_f)$ -action. Hence, the product  $X \times G(\mathbb{A}_f)/K$  is a countable union of copies of  $X$ . We consider the diagonal action

$$G(\mathbb{Q}) \curvearrowright X \times G(\mathbb{A}_f)/K.$$

If  $K$  is small enough then the  $G(\mathbb{Q})$ -action is free. (The technical term is “neat” and we will get to know it later in the course.) It is also properly discontinuous, so we can form the quotient complex manifold

$$\mathrm{Sh}_K(G, X)(\mathbb{C}) := G(\mathbb{Q}) \backslash (X \times G(\mathbb{A}_f) / K). \quad (1.6)$$

At this point, we have defined the complex points of the *Shimura variety for Shimura datum*  $(G, X)$  and level  $K$  as a complex manifold. The theorem of Baily–Borel states that there is a unique way to endow it with an algebraic structure.

**Theorem 1.3** (Baily–Borel, see [12, Corollary 3.16]). *There exists a quasi-projective complex variety  $\mathrm{Sh}_K(G, X)_{\mathbb{C}}$  such that there exists an isomorphism of complex manifolds  $\mathrm{Sh}_K(G, X)_{\mathbb{C}}(\mathbb{C}) \xrightarrow{\sim} \mathrm{Sh}_K(G, X)(\mathbb{C})$ . This variety is unique up to isomorphism.*

**Remark 1.4.** Simple examples of non-unique algebraic structures on complex manifolds can be found in [7].

**Example 1.5.** Let us again consider the case  $G = \mathrm{GL}_2$  and let us give an example of a connected component of (1.6). Let  $\widehat{\mathbb{Z}} = \prod_{p < \infty} \mathbb{Z}_p$  be the subring of integral elements of  $\mathbb{A}_f$ . For  $n \geq 1$ , consider the kernel

$$K(n) = \ker (\mathrm{GL}_2(\widehat{\mathbb{Z}}) \longrightarrow \mathrm{GL}_2(\mathbb{Z}/n\mathbb{Z}))$$

which is an open compact subgroup of  $G(\mathbb{A}_f)$ . It is small enough (in the above sense) if  $n \geq 3$ . The intersection

$$\Gamma(n) := \mathrm{GL}_2(\mathbb{Q}) \cap K(n)$$

is the classical congruence subgroup

$$\Gamma(n) = \left\{ \gamma \in \mathrm{GL}_2(\mathbb{Z}) \mid \gamma \equiv \begin{pmatrix} 1 & \\ & 1 \end{pmatrix} \pmod{n} \right\}.$$

The quotients  $\Gamma(n) \backslash \mathbb{H}^+$  and  $\Gamma(n) \backslash \mathbb{H}^-$  will be two of the connected components of the complex manifold  $\mathrm{Sh}_{K(n)}(\mathrm{GL}_2, \mathbb{H}^{\pm})$ .

**1.7. Shimura varieties over number fields.** Finally, one descends  $\mathrm{Sh}_K(G, X)$  to a number field. Starting from a Shimura datum  $(G, X)$ , Deligne defines a number field  $E \subset \mathbb{C}$  called the *reflex field*. In a suitable sense, it is the smallest field over which the conjugacy class  $X$  is defined.

**Example 1.6.** Consider the three examples from §1.5.

- If  $G = \mathrm{GL}_2$  or more generally  $G = \mathrm{GSp}_{2g}$ , then the reflex field is  $\mathbb{Q}$ .
- If  $G = U(V)$  is a non-definite unitary group for an imaginary-quadratic field  $K/\mathbb{Q}$ , then the reflex field is the subfield  $E \subset \mathbb{C}$  that is isomorphic to  $K$ .

Deligne [2] gave a definition of *canonical model* of  $\mathrm{Sh}_K(G, X)_{\mathbb{C}}$  over  $E$ . It is a variety  $\mathrm{Sh}_K(G, X)$  over  $\mathrm{Spec}(E)$  together with an isomorphism

$$\mathbb{C} \otimes_E \mathrm{Sh}_K(G, X) \xrightarrow{\sim} \mathrm{Sh}_K(G, X)_{\mathbb{C}}$$

that satisfies a certain reciprocity law for complex multiplication points. Deligne proves that the canonical model  $\mathrm{Sh}_K(G, X)$  is unique up to isomorphism if it exists.

**Theorem 1.7** (Borovoi, Milne [10]). *For every Shimura datum, the canonical model exists.*

**Definition 1.8.** Let  $(G, X)$  be a Shimura datum with reflex field  $E$  and let  $K \subset G(\mathbb{A}_f)$  be a sufficiently small level subgroup. The Shimura variety of level  $K$  attached to  $(G, X)$  is the canonical model  $\mathrm{Sh}_K(G, X)$  from Theorem 1.7.

**Remark 1.9.** Historically, the study of Shimura varieties started with Shimura in the 1960s. He first considered moduli spaces of abelian varieties with **P**olarization, **E**ndomorphisms, and **L**evel structure (PEL). These are the Shimura varieties defined by *PEL type* Shimura data.

Shimura also studied several non-PEL cases and defined the corresponding Shimura varieties as varieties over number fields. Deligne [2] gave a group-theoretic framework for Shimura's work. His definition in terms of a reciprocity law for complex multiplication points is extrapolated from the Shimura–Taniyama reciprocity law for abelian varieties with complex multiplication. Deligne also constructed the canonical model for abelian type Shimura varieties. The proof of existence in the general case was completed by Milne based on ideas of Borovoi. See here for a short summary of the history by Milne [11, §6].

**Example 1.10.** Consider the two cases from Example 1.6. The unitary group  $U(V)$  has no PEL type Shimura data. For the group  $\mathrm{GSp}_{2g}$ , there exists a PEL type Shimura datum  $(\mathrm{GSp}_{2g}, X)$ . Consider a principal congruence level subgroup

$$K(n) = \ker (\mathrm{GSp}_{2g}(\widehat{\mathbb{Z}}) \longrightarrow \mathrm{GSp}_{2g}(\mathbb{Z}/n\mathbb{Z}))$$

with  $n \geq 3$ . Then the canonical model  $\mathrm{Sh}_{K(n)}(\mathrm{GSp}_{2g}, X)$  can be described as a moduli space of principally polarized abelian varieties with level- $n$ -structure. For example, if we look at  $\mathbb{C}$ -points and specialize to  $\mathrm{GL}_2$ , then we obtain

$$\mathrm{Sh}_{K(n)}(\mathrm{GL}_2, X)(\mathbb{C}) \xrightarrow{\sim} \{(E, \eta)/\mathbb{C}\} / \sim \quad (1.7)$$

where the right hand side denotes the set of isomorphism classes of pairs  $(E, \eta)$  with

- $E$  an elliptic curve over  $\mathbb{C}$ ,
- $\eta : (\mathbb{Z}/n\mathbb{Z})^{\oplus 2} \xrightarrow{\sim} E[n]$  a choice of basis for the  $n$ -torsion.

The datum  $\eta$  is called a *level structure* for  $E$ . Proving (1.7) will be one of our first goals.

**1.8. Further topics.** We will say more about this when the time comes. For now, let us start looking at Shimura varieties in detail.

## Part 1. The Shimura variety of $\mathrm{GL}_2$

### 2. THE UPPER HALF PLANE

In Example 1.1, we have introduced the action of  $\mathrm{GL}_2(\mathbb{Q})$  on the union of upper and lower half plane  $\mathbb{H}^\pm = \mathbb{C} \setminus \mathbb{R}$ . Recall that it is given by

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \cdot \tau = \frac{a\tau + b}{c\tau + d}.$$

In Example 1.5, we have seen that we are especially interested in actions by subgroups such as  $\mathrm{GL}_2(\mathbb{Z})$  and  $\Gamma(n)$ . Our aim in this section is to give a definition of such *arithmetic subgroups* and to prove properties about their action on  $\mathbb{H}^\pm$ .

Note that elements of  $\mathrm{GL}_2(\mathbb{Z})$  have determinant 1 or  $-1$ , and that the elements of determinant  $-1$  interchange upper and lower half plane. So we will focus on the action of  $\mathrm{SL}_2(\mathbb{Q})$  on the upper half plane  $\mathbb{H} \subset \mathbb{H}^\pm$ .

**2.1. The fundamental domain.** Let  $\mathcal{F}$  be the area defined by

$$\mathcal{F} = \left\{ \tau \in \mathbb{H} \mid |\tau| \geq 1 \text{ and } -\frac{1}{2} \leq \operatorname{Re}(\tau) \leq \frac{1}{2} \right\}. \quad (2.1)$$

Its interior  $\mathcal{F}^\circ$  is the open subset where  $|\tau| > 1$  and  $-1/2 \leq \operatorname{Re}(\tau) \leq 1/2$ .

FIGURE 1. The area  $\mathcal{F}$  is depicted in grey. The remaining areas show translates of  $\mathcal{F}$  under the action of the elements  $S$  and  $T$  defined in (2.3). By Proposition 2.1 and Remark 2.2, these translates cover all of  $\mathbb{H}$ . The picture is taken from [14, §VII].

**Proposition 2.1.** *The set  $\mathcal{F}$  is a fundamental domain for the action of  $\mathrm{SL}_2(\mathbb{Z})/\{\pm 1\}$  on  $\mathbb{H}$ . That is, it has the following two properties.*

- (1) *For every  $\tau \in \mathbb{H}$ , there exists  $\gamma \in \mathrm{SL}_2(\mathbb{Z})$  such that  $\gamma\tau \in \mathcal{F}$ .*
- (2)  *$\mathcal{F}^\circ \cap \gamma\mathcal{F}^\circ = \emptyset$  whenever  $\gamma \notin \{\pm 1\}$ .*

*Proof.* Fix  $\tau \in \mathbb{H}$  and let  $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z})$  be any element. By direct computation, we see that

$$\operatorname{Im}(\gamma\tau) = \operatorname{Im}\left(\frac{(a\tau + b)(c\tau - d)}{|c\tau + d|^2}\right) = \frac{(ad - bc)\operatorname{Im}(\tau)}{|c\tau + d|^2} = \frac{\operatorname{Im}(\tau)}{|c\tau + d|^2}. \quad (2.2)$$

The denominator  $|c\tau + d|^2$  defines a positive definite quadratic form in  $(c, d) \in \mathbb{Z}^2$ . It hence takes a minimum on the set of  $(c, d)$  that occur as the bottom row of an element of  $\mathrm{SL}_2(\mathbb{Z})$ . (These are precisely the  $(c, d)$  with  $\gcd(c, d) = 1$ .) So we see that  $\{\operatorname{Im}(\gamma\tau) \mid \gamma \in \mathrm{SL}_2(\mathbb{Z})\}$  has a maximum.

Let  $\gamma$  be such that  $\text{Im}(\gamma\tau)$  is maximal. Consider the two matrices

$$S = \begin{pmatrix} & 1 \\ -1 & \end{pmatrix}, \quad T = \begin{pmatrix} 1 & 1 \\ & 1 \end{pmatrix} \quad (2.3)$$

and observe that they act as the very simple transformations

$$S\tau = -\frac{1}{\tau}, \quad T\tau = \tau + 1. \quad (2.4)$$

In particular, acting with a suitable power  $T^m$ ,  $m \in \mathbb{Z}$ , we can translate  $\gamma\tau$  to assume it lies in the strip  $-1/2 \leq \text{Re}(z) \leq 1/2$ . Then also  $|\gamma\tau| \geq 1$  because otherwise  $\text{Im}(S\gamma\tau) > \text{Im}(\gamma\tau)$  would contradict the maximality of  $\text{Im}(\gamma\tau)$ . This proves statement (1) of the proposition.

We now prove statement (2). Assume that  $\tau$  and  $\gamma\tau$  both lie in  $\mathcal{F}^\circ$ , our aim being to show that  $\gamma \in \{\pm 1\}$ . After possibly replacing the pair  $(\gamma, \tau)$  by  $(\gamma^{-1}, \gamma\tau)$ , we can assume that  $\text{Im}(\gamma\tau) \geq \text{Im}(\tau)$ . Considering again (2.2), this means that  $|c\tau + d|^2 \leq 1$ .

Clearly, we now have  $c = 0$  because  $|c\tau + d| > 1$  for every  $c \neq 0$  (use  $\tau \in \mathcal{F}^\circ$ ). This means that  $\gamma$  is of the form

$$\gamma = \pm \begin{pmatrix} 1 & m \\ & 1 \end{pmatrix}$$

for some  $m \in \mathbb{Z}$ . Since both  $\tau$  and  $\gamma\tau$  have real part in  $(-1/2, 1/2)$ , the only possibility is  $m = 0$ . This finishes the proof.  $\square$

**Remark 2.2.** One can show that the matrices  $S$  and  $T$  from (2.3) generate  $\text{SL}_2(\mathbb{Z})$ . That is, every element of  $\text{SL}_2(\mathbb{Z})$  can be written as a product of the three elements  $S$ ,  $T$  and  $T^{-1}$ . The proof is not difficult and can be found in [14, §VII.1, Theorem 2].

**2.2. Arithmetic subgroups of  $\text{SL}_2(\mathbb{Q})$ .** We now define arithmetic subgroups of  $\text{SL}_2(\mathbb{Q})$ .

**Definition 2.3.** (1) For  $n \geq 1$ , we define the *principal congruence subgroup*  $\Gamma(n)$  by

$$\Gamma(n) = \{\gamma \in \text{SL}_2(\mathbb{Z}) \mid \gamma \equiv 1 \pmod{n}\}.$$

(2) We call a subgroup  $\Gamma \subset \text{SL}_2(\mathbb{Q})$  *arithmetic* if it contains a principal congruence group  $\Gamma(n)$  with finite index.

The group  $\text{SL}_2$  has a very interesting property which will come up again later. Namely, for each  $n \geq 1$ , the projection map

$$\text{SL}_2(\mathbb{Z}) \longrightarrow \text{SL}_2(\mathbb{Z}/n\mathbb{Z}) \quad (2.5)$$

is surjective. This is not hard to show directly, but also follows from Theorem 3.15 (2) below.

**Example 2.4.** By the surjectivity we just stated for  $\text{SL}_2$ , the image of the projection map  $\text{GL}_2(\mathbb{Z}) \rightarrow \text{GL}_2(\mathbb{Z}/n\mathbb{Z})$  is the set of matrices with determinant  $\pm 1$ . In particular, this projection is not surjective when  $n = 5$  or  $n \geq 7$ .

In the context of Definition 2.3, the surjectivity of (2.5) implies that  $\Gamma(n) \trianglelefteq \text{SL}_2(\mathbb{Z})$  is a normal subgroup of index equal to  $|\text{SL}_2(\mathbb{Z}/n\mathbb{Z})|$ . In particular, if a group  $\Gamma$  contains  $\Gamma(n)$  with finite index, then it also contains all  $\Gamma(mn)$  with finite index.

**Proposition 2.5.** *Let  $\Gamma$  be an arithmetic subgroup.*

(1) *There exists a lattice  $\Lambda \subset \mathbb{Q}^2$  such that  $\Gamma \subseteq \text{SL}(\Lambda)$ .*

(2) *More precisely, there exist an integer  $n$  and an element  $g \in \text{GL}_2(\mathbb{Q})$ ,  $\det(g) > 0$ , such that*

$$\Gamma(m) \subseteq g\Gamma g^{-1} \subseteq \text{SL}_2(\mathbb{Z}).$$

*Proof.* The two statements are proved by very simple and universal arguments. First, by assumption on  $\Gamma$ , there exists an integer  $n$  such that  $\Gamma(n) \subseteq \Gamma$  with finite index. Let  $\gamma_1, \dots, \gamma_r$  be representatives for the cosets  $\Gamma/\Gamma(n)$ . Then  $\Gamma$  stabilizes the lattice

$$\Lambda := \sum_{i=1}^r \gamma_i \cdot \mathbb{Z}^2.$$

Indeed, since  $\gamma\mathbb{Z}^2 = \mathbb{Z}^2$  for every  $\gamma \in \Gamma(n)$ , we can also write  $\Lambda$  as

$$\Lambda = \sum_{\gamma \in \Gamma} \gamma \cdot \mathbb{Z}^2,$$

and from this second expression the  $\Gamma$ -stability is clear. This means that  $\Gamma \subseteq \mathrm{SL}(\Lambda)$  which proves statement (1).

Let  $\lambda_1, \lambda_2 \in \Lambda$  be a basis as  $\mathbb{Z}$ -module. Viewing  $\lambda_1$  and  $\lambda_2$  as column vectors, the base change matrix  $g = (\lambda_1 \ \lambda_2)$  lies in  $\mathrm{GL}_2(\mathbb{Q})$  and has the property  $g\mathbb{Z}^2 = \Lambda$ . Changing  $\lambda_1$  to  $-\lambda_1$  if necessary, we may assume  $\det(g) > 0$ . Then  $\mathrm{SL}_2(\mathbb{Z}) = g^{-1}\mathrm{SL}(\Lambda)g$  and hence  $g\Gamma g^{-1} \subseteq \mathrm{SL}_2(\mathbb{Z})$ .

We still need to show that  $g\Gamma g^{-1}$  contains a principal congruence subgroup. This is the content of the next lemma which completes the proof.  $\square$

**Lemma 2.6.** *Let  $\Gamma \subset \mathrm{SL}_2(\mathbb{Q})$  be an arithmetic subgroup and  $g \in \mathrm{GL}_2(\mathbb{Q})$ . Then  $g\Gamma g^{-1}$  is again an arithmetic subgroup.*

*Proof.* Let  $d$  be the least common multiple of all the denominators of all the entries of  $g$  and  $g^{-1}$ . Then, if  $A \in d^2m\mathrm{M}_2(\mathbb{Z})$  is an integer matrix divisible by  $d^2m$ , we find  $g^{-1}Ag \in m\mathrm{M}_2(\mathbb{Z})$ . This shows that  $g^{-1}\Gamma(d^2m)g \subseteq \Gamma(m)$  which is equivalent to

$$\Gamma(d^2m) \subseteq g\Gamma(m)g^{-1}. \quad (2.6)$$

Now, for the given  $\Gamma$ , choose  $n$  with  $\Gamma(n) \subseteq \Gamma$ . Conjugating this relation by  $g$  and using (2.6), we find  $\Gamma(d^2n) \subseteq g\Gamma g^{-1}$  which proves that  $g\Gamma g^{-1}$  is again arithmetic.  $\square$

In other words, Proposition 2.5 shows that the arithmetic subgroups in  $\mathrm{SL}_2(\mathbb{Q})$  are precisely the  $\mathrm{GL}_2(\mathbb{Q})$ -conjugates of groups between  $\mathrm{SL}_2(\mathbb{Z})$  and some  $\Gamma(n)$ .

### 2.3. Stabilizers.

**Definition 2.7.** We say that an arithmetic subgroup  $\Gamma \subset \mathrm{SL}_2(\mathbb{Q})$  is *neat* if it is torsion free.

**Proposition 2.8.** *Let  $\Gamma$  be a neat arithmetic subgroup of  $\mathrm{SL}_2(\mathbb{Q})$ . Then  $\Gamma$  acts with trivial stabilizers on  $\mathbb{H}$ . That is, if  $\gamma\tau = \tau$  for some  $\gamma \in \Gamma$  and  $\tau \in \mathbb{H}$ , then  $\gamma = 1$ .*

*Proof.* We have seen in (1.4) that the stabilizer of  $i \in \mathbb{H}$  in  $\mathrm{GL}_2(\mathbb{R})$  is a copy of  $\mathbb{C}^\times$ . The unit circle  $\mathbb{C}^1 \subset \mathbb{C}^\times$  is compact and equals the intersection  $\mathbb{C}^\times \cap \mathrm{SL}_2(\mathbb{R})$ . For a general point  $\tau \in \mathbb{H}$ , we can write  $\tau = g \cdot i$  for some  $g \in \mathrm{SL}_2(\mathbb{R})$ :

$$\begin{pmatrix} 1 & b \\ & 1 \end{pmatrix} \begin{pmatrix} a^{1/2} & \\ & a^{-1/2} \end{pmatrix} \cdot i = ai + b.$$

The stabilizers  $S_i$  and  $S_\tau$  of  $\tau$  and  $i$  in  $\mathrm{SL}_2(\mathbb{R})$  are then related by  $S_\tau = gS_i g^{-1}$ . In this way, we see that for every  $\tau \in \mathbb{H}$ , the stabilizer  $S_\tau \subset \mathrm{SL}_2(\mathbb{R})$  is isomorphic to  $\mathbb{C}^1$ , in particular compact.

Assume that  $\gamma\tau = \tau$ , where  $\gamma \in \Gamma$  and  $\tau \in \mathbb{H}$ . This is equivalent to  $\gamma \in \Gamma \cap S_\tau$ . Since  $\Gamma \subset \mathrm{SL}_2(\mathbb{R})$  is a discrete subgroup, the intersection  $\Gamma \cap S_\tau$  is a discrete subgroup of  $S_\tau$ . Since the discrete subgroups of  $\mathbb{C}^1$  are all finite cyclic (generated by a root of unity), and since  $\Gamma$  is torsion-free by assumption, we see that  $\Gamma \cap S_\tau = \{1\}$ . Hence  $\gamma = 1$ , and the proof is complete.  $\square$

The next proposition provides a simple criterion for detecting neatness.

**Proposition 2.9.** *For all  $n \geq 3$ , the principal congruence subgroup  $\Gamma(n)$  is neat. In particular, if  $\Gamma \subseteq \Gamma(n)$  is an arithmetic subgroup, then  $\Gamma$  is neat.*

*Proof.* The minimal polynomial  $\Phi_d(T)$  of a primitive  $d$ -th root of unity has degree  $\varphi(d)$  (Euler  $\varphi$ -function). Recall that  $\Phi_d(T)$  is called the  $d$ -th cyclotomic polynomial and that

$$T^m - 1 = \prod_{d|m} \Phi_d(T)$$

because the roots of  $T^m - 1$  are precisely the  $m$ -th roots of unity, and each such root of unity is a primitive  $d$ -th root of unity for a unique divisor  $d \mid m$ .

The only values for  $d$  such that  $\varphi(d) \leq 2$  are 1, 2, 3, 4, and 6. These are precisely the values for  $d$  such that  $\mathbb{Q}(\zeta_d)$  has degree  $\leq 2$  over  $\mathbb{Q}$ .

Let  $n \geq 1$  and let  $\gamma \in \mathrm{SL}_2(\mathbb{Q})$  be a torsion element, say  $\gamma^m = 1$ . Then the minimal polynomial of  $\gamma$  divides  $T^m - 1$ . We know that the minimal polynomial and the characteristic polynomial of a matrix have the same irreducible factors. So the characteristic polynomial  $P(T)$  of  $\gamma$  is a product of  $\Phi_d(T)$  with  $d \mid m$ . The only possibilities for  $P(T)$  are hence<sup>1</sup>

$$(T-1)^2, (T+1)^2, (T-1)(T+1), T^2+1, T^2+T+1, \text{ and } T^2-T+1. \quad (2.7)$$

If  $n \geq 3$  and if  $\gamma$  is integral with  $\gamma \equiv 1 \pmod{n}$ , then also  $P(T) \equiv (T-1)^2 \pmod{n}$ , leaving  $P(T) = (T-1)^2$  as the only possibility. This means that  $\gamma$  is either equal to 1 or  $\mathrm{GL}_2(\mathbb{Q})$ -conjugate to  $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$  (Jordan normal form). But  $\gamma$  is also a torsion element by assumption, so  $\gamma = 1$  is the only possibility.  $\square$

**Exercise 2.10.** Extend the argument of the previous proof to  $\mathrm{GL}_n$ . That is, given  $n \geq 1$ , find an integer  $m \geq 1$  such that for  $\gamma \in \mathrm{GL}_n(\mathbb{Z})$ ,

$$\gamma \equiv 1 \pmod{m} \implies \gamma \text{ non-torsion}.$$

**Conclusion 2.11.** In this lecture, we saw the definition of neat arithmetic subgroups of  $\mathrm{SL}_2(\mathbb{Q})$ . We have seen in Proposition 2.8 that such groups act freely on  $\mathbb{H}$ . So the quotient  $\Gamma \backslash \mathbb{H}$  will be a Riemann surface and the quotient map

$$\mathbb{H} \longrightarrow \Gamma \backslash \mathbb{H} \quad (2.8)$$

a holomorphic covering map in the sense of topology. We have seen in Proposition 2.5 that, in order to study  $\Gamma \backslash \mathbb{H}$ , we may always assume  $\Gamma \subseteq \mathrm{SL}_2(\mathbb{Z})$ . Then we can think of  $\Gamma \backslash \mathbb{H}$  as being glued from finitely many  $\mathrm{SL}_2(\mathbb{Z})$ -translates of the fundamental domain  $\mathcal{F}$  as in Figure 2.1 along their edges.

---

<sup>1</sup>The product  $(T-1)(T+1)$  cannot actually occur, of course, because  $\det(\gamma) = 1$  for  $\gamma \in \mathrm{SL}_2(\mathbb{Q})$ . This does not affect the argument, though.

### 3. ADELIC DOUBLE QUOTIENTS

In this lecture, we study the adelic double quotients  $\mathrm{GL}_2(\mathbb{Q}) \backslash (\mathbb{H}^\pm \times \mathrm{GL}_2(\mathbb{A}_f)/K)$  and relate them to the quotients  $\Gamma \backslash \mathbb{H}$  from the previous lecture. We will first revisit the definition of the adeles and explain the definition of  $\mathrm{GL}_2(\mathbb{A}_f)$  as a topological group in more detail. In fact, we will use this opportunity to also study groups of the form  $G(\mathbb{A}_f)$  more generally.

**3.1. The adeles.** We begin by defining the ring of *integral adeles*. It is the profinite ring given by<sup>2</sup>  $\widehat{\mathbb{Z}} := \varprojlim \mathbb{Z}/n\mathbb{Z}$ . The transition maps here are given by the projections  $\mathbb{Z}/m\mathbb{Z} \rightarrow \mathbb{Z}/n\mathbb{Z}$ , whenever  $m \mid n$ . Concretely, we have

$$\widehat{\mathbb{Z}} = \left\{ (x_1, x_2, \dots) \in \prod_{n \geq 1} \mathbb{Z}/n\mathbb{Z} \mid x_{dn} \equiv x_n \pmod{n} \text{ for all } d, n \geq 1 \right\}.$$

Recall that the Chinese remainder theorem identifies  $\mathbb{Z}/n\mathbb{Z} \xrightarrow{\sim} \prod_p \mathbb{Z}/p^{v_p(n)}\mathbb{Z}$ . If we apply this identification to each term of the limit, then we obtain an isomorphism

$$\widehat{\mathbb{Z}} \xrightarrow{\sim} \prod_p \mathbb{Z}_p, \quad (x_1, x_2, \dots) \mapsto ((x_1, x_p, x_{p^2}, \dots))_p. \quad (3.1)$$

We endow each  $\mathbb{Z}_p$  with the usual  $p$ -adic topology and their product with the product topology. Then (3.1) is an isomorphism of topological rings.

**Definition 3.1.** The *ring of finite adeles* is defined by  $\mathbb{A}_f := \mathbb{Q} \otimes_{\mathbb{Z}} \widehat{\mathbb{Z}}$ . Since  $\widehat{\mathbb{Z}}$  is torsion-free, we can view it as a subring  $\widehat{\mathbb{Z}} \subset \mathbb{A}_f$ . We endow  $\mathbb{A}_f$  with the topology such that  $\widehat{\mathbb{Z}}$  is an open subring.

Let us unravel this definition. First, on the level of rings,  $\mathbb{A}_f$  is the ring of fractions  $x/m$  with  $x \in \widehat{\mathbb{Z}}$  and  $m \geq 1$ , where the usual rules of arithmetic apply. Using (3.1), we can more explicitly describe it as the subring

$$\mathbb{A}_f = \left\{ (x_p) \in \prod_p \mathbb{Q}_p \mid x_p \in \mathbb{Z}_p \text{ for almost all } p \right\}.$$

Now we describe the topology. In  $\widehat{\mathbb{Z}}$ , a neighborhood basis of 0 is given by all the kernels of the projections  $\widehat{\mathbb{Z}} \rightarrow \mathbb{Z}/n\mathbb{Z}$ . These are precisely the ideals  $n\widehat{\mathbb{Z}}$ . Under the isomorphism (3.1), they are the subsets of the form

$$\prod_{p \in S} p^{m_p} \mathbb{Z}_p \times \prod_{p \notin S} \mathbb{Z}_p$$

where  $S$  is a finite set of primes and  $(m_p)_{p \in S}$  a tuple of non-negative integers. Such sets forming a neighborhood basis of 0 means that the sets

$$\{x + n\widehat{\mathbb{Z}} \mid x \in \widehat{\mathbb{Z}}, n \geq 1\} \quad (3.2)$$

give a basis of the topology on  $\widehat{\mathbb{Z}}$ . Declaring  $\widehat{\mathbb{Z}} \subset \mathbb{A}_f$  an open subring then simply means that the sets  $n\widehat{\mathbb{Z}}$  also form a neighborhood basis of 0 in  $\mathbb{A}_f$ . Equivalently, the sets

$$\{x + n\widehat{\mathbb{Z}} \mid x \in \mathbb{A}_f, n \geq 1\} \quad (3.3)$$

provide a basis for the topology on  $\mathbb{A}_f$ .

**Definition 3.2.** The ring of adeles is defined as the product  $\mathbb{A} := \mathbb{A}_f \times \mathbb{R}$  endowed with the product topology.

**Proposition 3.3.** *The subring  $\mathbb{Q} \subset \mathbb{A}$  is discrete.*

<sup>2</sup>We use  $\varprojlim$  and  $\varinjlim$  to denote the limit and the colimit. In other references, these might be called  $\varprojlim$  and  $\varinjlim$ .

*Proof.* By definitions, the product  $U = \widehat{\mathbb{Z}} \times (-1, 1)$  is an open subset of  $\mathbb{A}$ . The intersection  $U \cap \mathbb{Q}$  consists of those rational numbers that lie in  $\mathbb{Z} = \widehat{\mathbb{Z}} \cap \mathbb{Q}$  and in the interval  $(-1, 1)$ . In other words,  $U \cap \mathbb{Q} = \{0\}$ . Thus,  $\{0\} \subset \mathbb{Q}$  is an open subset for the subspace topology. By additive translation invariance of the topology ( $\mathbb{A}$  is a topological ring), the same argument applies for all rational numbers. This shows that the subspace topology on  $\mathbb{Q}$  is the discrete topology as claimed.  $\square$

Let  $F/\mathbb{Q}$  be a finite extension. The adeles of  $F$  can be defined in the same way as for  $\mathbb{Q}$ . First, we define the integral adeles with profinite topology

$$\widehat{O}_F := \lim_{\mathfrak{a} \subseteq O_F} O_F/\mathfrak{a} \xrightarrow{\sim} \prod_{\mathfrak{p}} O_{F,\mathfrak{p}}. \quad (3.4)$$

Then we tensor by  $\mathbb{Q}$  over  $\mathbb{Z}$ , or equivalently by  $F$  over  $O_F$ , to define the finite adeles:

$$\begin{aligned} \mathbb{A}_{F,f} &:= \mathbb{Q} \otimes_{\mathbb{Z}} \widehat{O}_F \\ &\xrightarrow{\sim} \left\{ (x_{\mathfrak{p}}) \in \prod_{\mathfrak{p}} F_{\mathfrak{p}} \mid x_{\mathfrak{p}} \in O_{F,\mathfrak{p}} \text{ for almost all } \mathfrak{p} \right\}. \end{aligned} \quad (3.5)$$

Again, the topology on  $\mathbb{A}_{F,f}$  is defined by declaring  $\widehat{O}_F$  to be an open subring. Finally, we define the adeles as the product

$$\mathbb{A}_F := \mathbb{A}_{F,f} \times (\mathbb{R} \otimes_{\mathbb{Q}} F) \xrightarrow{\sim} \mathbb{A}_{F,f} \times \prod_{\sigma:F \rightarrow \mathbb{R}} \mathbb{R} \times \prod_{\{\sigma, \bar{\sigma}\}: F \rightarrow \mathbb{C}} \mathbb{C}. \quad (3.6)$$

Here, the real factors have their real vector space topology, and the last two products are over the real (resp. complex) places of  $F$ .

Recall that  $O_F$  is a free abelian group of rank equal to  $d = [F : \mathbb{Q}]$ . Let  $\alpha_1, \dots, \alpha_d$  be a  $\mathbb{Z}$ -module basis of  $O_F$ . Such a choice provides isomorphisms of  $\widehat{\mathbb{Z}}$ -,  $\mathbb{A}_f$ -, resp.  $\mathbb{A}$ -modules

$$\widehat{\mathbb{Z}}^n \xrightarrow{\sim} O_F \otimes_{\mathbb{Z}} \widehat{\mathbb{Z}}, \quad \mathbb{A}_f^n \xrightarrow{\sim} F \otimes_{\mathbb{Q}} \mathbb{A}_f, \quad \mathbb{A}^n \xrightarrow{\sim} F \otimes_{\mathbb{Q}} \mathbb{A}. \quad (3.7)$$

We endow  $\widehat{\mathbb{Z}}^n$ ,  $\mathbb{A}_f^n$  and  $\mathbb{A}^n$  with the product topology and use the isomorphisms in (3.7) to define from this the topology on the three tensor products. This topology is independent of the choice of  $\alpha_1, \dots, \alpha_d$ .

**Remark 3.4.** The previous definition is a general principle. Let  $R$  be a topological ring and let  $M$  be a finite free  $R$ -module. Any choice of  $R$ -basis  $\alpha_1, \dots, \alpha_d$  defines an isomorphism  $R^d \xrightarrow{\sim} M$  and, in this way, endows  $M$  with a topology.

Any two such isomorphisms differ by an element of  $\mathrm{GL}_d(R)$ . Since the action of every  $g \in \mathrm{GL}_d(R)$  on  $R^d$  is continuous, the topology is independent of the chosen basis.

**Proposition 3.5.** *Multiplication defines isomorphisms of topological rings*

$$O_F \otimes_{\mathbb{Z}} \widehat{\mathbb{Z}} \xrightarrow{\sim} \widehat{O}_F, \quad F \otimes_{\mathbb{Q}} \mathbb{A}_f \xrightarrow{\sim} \mathbb{A}_{F,f}, \quad F \otimes_{\mathbb{Q}} \mathbb{A} \xrightarrow{\sim} \mathbb{A}_F.$$

*Proof.* Every ideal  $\mathfrak{a} \subseteq O_F$  contains an ideal  $nO_F$  with  $n \in \mathbb{Z}_{\geq 1}$ . So we can rewrite (3.4) as  $\widehat{O}_F = \lim O_F/nO_F$ . Having chosen  $\alpha_1, \dots, \alpha_d$ , we obtain

$$\begin{aligned} \widehat{O}_F &= \lim \left( \bigoplus_{i=1}^d \mathbb{Z}/n\mathbb{Z} \cdot \alpha_i \right) \\ &\xrightarrow{\sim} \bigoplus_{i=1}^d \left( \lim \mathbb{Z}/n\mathbb{Z} \right) \cdot \alpha_i \\ &\xrightarrow{\sim} \bigoplus_{i=1}^d \widehat{\mathbb{Z}} \cdot \alpha_i. \end{aligned}$$

This shows that  $O_F \otimes_{\mathbb{Z}} \widehat{\mathbb{Z}} \xrightarrow{\sim} \widehat{O}_F$  as topological rings. The statements for  $\mathbb{A}_{F,f}$  and  $\mathbb{A}_F$  follow from this.  $\square$

**Corollary 3.6.** *Let  $F/\mathbb{Q}$  be a finite extension. Then  $F \subset \mathbb{A}_F$  is discrete.*

*Proof.* Since  $\mathbb{Q}$  is discrete in  $\mathbb{A}$ , we have that  $\mathbb{Q}^n$  is discrete in  $\mathbb{A}^n$ . Choosing a  $\mathbb{Q}$ -basis  $\alpha = (\alpha_1, \dots, \alpha_d)$  for  $F$ , we obtain a commutative square of the form

$$\begin{array}{ccc} \mathbb{Q}^n & \hookrightarrow & \mathbb{A}^n \\ \alpha \parallel & & \parallel \alpha \\ F & \hookrightarrow & \mathbb{A}_F. \end{array}$$

By Proposition 3.5, the right vertical identification is a homeomorphism. Hence we obtain that  $F$  is discrete in  $\mathbb{A}_F$ .  $\square$

**3.2. Groups of the form  $G(\mathbb{A}_f)$ .** Let us formulate the problem more generally.

**Question 3.7.** Let  $X$  be an affine variety<sup>3</sup> over  $\mathbb{Q}$  and let  $R$  be a topological  $\mathbb{Q}$ -algebra. We assume that points of  $R$  are closed. For example,  $R$  could be  $\mathbb{R}$ ,  $\mathbb{C}$ ,  $\mathbb{Q}_p$ ,  $\mathbb{A}_f$  or  $\mathbb{A}$ . How to define the topological space  $X(R)$  in a natural way?

The answer is very simple. Let us write  $\mathcal{A}^N = \text{Spec } \mathbb{Q}[t_1, \dots, t_N]$  for affine  $N$ -space over  $\mathbb{Q}$  to avoid confusion with the adèle notation. We endow  $\mathcal{A}^N(R) = R^N$  with the product topology.

Let  $f_1, \dots, f_m \in \mathbb{Q}[t_1, \dots, t_N]$  be polynomials and let  $X = V(f_1, \dots, f_m) \subseteq \mathcal{A}^N$  be their vanishing locus. Then  $X(R) \subseteq R^N$  is a closed subset because it equals the intersection  $\cap_{i=1}^m f_i^{-1}(0)$ , and we endow it with the subspace topology.

**Definition 3.8.** Let  $X$  be an affine  $\mathbb{Q}$ -variety. Choose a presentation  $\varphi : X \xrightarrow{\sim} V(f_1, \dots, f_m)$  as above. The topology on  $X(R)$  is defined as the subspace topology with respect to  $\varphi(R) : X(R) \hookrightarrow R^N$ .

**Lemma 3.9.** *This topology on  $X(R)$  is independent of the choices of  $N$ ,  $(f_1, \dots, f_m)$  and  $\varphi$ .*

*Proof.* Assume that we are given two affine varieties  $V(f_1, \dots, f_{m_1}) \subseteq \mathcal{A}^{N_1}$  as well as  $V(g_1, \dots, g_{m_2}) \subseteq \mathcal{A}^{N_2}$ . Assume that

$$\varphi : V(f_1, \dots, f_{m_1}) \xrightarrow{\sim} V(g_1, \dots, g_{m_2})$$

is an isomorphism of  $\mathbb{Q}$ -varieties. Then  $\varphi$  and  $\psi = \varphi^{-1}$  lift to morphisms  $\Phi : \mathcal{A}^{N_1} \rightarrow \mathcal{A}^{N_2}$  and  $\Psi : \mathcal{A}^{N_2} \rightarrow \mathcal{A}^{N_1}$ . The induced maps

$$R^{N_1} \begin{array}{c} \xrightarrow{\Phi} \\ \xleftarrow{\Psi} \end{array} R^{N_2}$$

are continuous because they are given by polynomials. Hence their restrictions  $\varphi$  and  $\psi$  are continuous as well. Since  $\psi = \varphi^{-1}$ , this shows that  $\varphi$  is a homeomorphism.  $\square$

**Example 3.10.** Consider the group variety  $\text{GL}_n$ . One possible presentation as a closed subset of an affine space is given by

$$\begin{aligned} \text{GL}_n &\xrightarrow{\sim} V(1 - t \cdot \det((t_{ij})_{i,j=1}^n)) \subset \mathcal{A} \times_{\text{Spec}(\mathbb{Q})} \mathcal{A}^{n^2} \\ g = (t_{ij})_{i,j=1}^n &\longmapsto (\det(g)^{-1}, g). \end{aligned}$$

For example, if  $n = 1$ , we recover the closed immersion<sup>4</sup>

$$\mathbb{G}_m \hookrightarrow \mathcal{A}^2, \quad t \longmapsto (t^{-1}, t).$$

<sup>3</sup>More generally, an affine finite type  $\mathbb{Q}$ -scheme.

<sup>4</sup> $\mathbb{G}_m$  is just another notation for  $\text{GL}_1$ . The notation symbolizes *multiplicative group*.

According to Definition 3.8, the topology on  $\mathrm{GL}_n(\mathbb{A}_f)$  is then given as the subspace topology with respect to

$$\mathrm{GL}_n(\mathbb{A}_f) \hookrightarrow \mathbb{A}_f \times \mathrm{M}_n(\mathbb{A}_f), \quad g \mapsto (\det(g)^{-1}, g).$$

The product  $\widehat{\mathbb{Z}} \times \mathrm{M}_n(\widehat{\mathbb{Z}})$  is an open subset on the right hand side. So the intersection

$$\mathrm{GL}_n(\widehat{\mathbb{Z}}) = \mathrm{GL}_n(\mathbb{A}_f) \cap (\widehat{\mathbb{Z}} \times \mathrm{M}_n(\widehat{\mathbb{Z}}))$$

is an open subset of  $\mathrm{GL}_n(\mathbb{A}_f)$ . (The elements of  $\mathrm{GL}_n(\widehat{\mathbb{Z}})$  are precisely those elements of  $\mathrm{GL}_n(\mathbb{A}_f) \cap \mathrm{M}_n(\widehat{\mathbb{Z}})$  whose inverse determinant again lies in  $\widehat{\mathbb{Z}}$ .) As a closed subset of the profinite set  $\widehat{\mathbb{Z}} \times \mathrm{M}_n(\widehat{\mathbb{Z}})$ ,  $\mathrm{GL}_n(\widehat{\mathbb{Z}})$  is again profinite. In fact, we have

$$\mathrm{GL}_n(\widehat{\mathbb{Z}}) \xrightarrow{\sim} \lim_{m \geq 1} \mathrm{GL}_n(\mathbb{Z}/m\mathbb{Z})$$

as topological group. The principal congruence subgroups

$$K(m) := \ker(\mathrm{GL}_n(\widehat{\mathbb{Z}}) \longrightarrow \mathrm{GL}_n(\mathbb{Z}/m\mathbb{Z}))$$

form a neighborhood basis of 1 in  $\mathrm{GL}_n(\mathbb{A}_f)$ .

**Example 3.11.** We always view  $\mathbb{A}_f^\times$  with the topology coming from  $\mathbb{A}_f^\times = \mathbb{G}_m(\mathbb{A}_f)$ . Then the inclusion map  $\mathbb{A}_f^\times \rightarrow \mathbb{A}_f$  is continuous because it is induced from the morphism of varieties  $\mathbb{G}_m \rightarrow \mathcal{A}$ ,  $t \mapsto t$ . But it is not an open immersion. For example,  $\widehat{\mathbb{Z}}^\times$  is open in  $\mathbb{A}_f^\times$ , but not in  $\mathbb{A}_f$ .

**Exercise 3.12.** Prove the claim in the previous example. That is, show that none of the open subsets  $1 + n\widehat{\mathbb{Z}} \subseteq \widehat{\mathbb{Z}}$ , which form a neighborhood basis of  $1 \in \widehat{\mathbb{Z}}$ , is contained in  $\widehat{\mathbb{Z}}^\times$ .

**Example 3.13.** Let  $G$  be a general linear algebraic group over  $\mathbb{Q}$ . There always exist some  $N \geq 1$  and a closed immersion  $G \hookrightarrow \mathrm{GL}_N$ . Then  $G(\mathbb{A}_f) \subseteq \mathrm{GL}_N(\mathbb{A}_f)$  has the subspace topology. In particular, the intersections  $G(\mathbb{A}_f) \cap K(m)$  with all congruence subgroups form a neighborhood basis of  $1 \in G(\mathbb{A}_f)$ .

This applies, for example, to the standard representations

$$\mathrm{SL}_2 \hookrightarrow \mathrm{GL}_2, \quad \mathrm{Sp}_{2g} \hookrightarrow \mathrm{GL}_{2g}, \quad \mathrm{GSp}_{2g} \hookrightarrow \mathrm{GL}_{2g}.$$

Let  $V$  be a quadratic  $\mathbb{Q}$ -vector space. Then it applies to the closed immersions

$$\mathrm{SO}(V) \hookrightarrow \mathrm{GL}(V), \quad \mathrm{O}(V) \hookrightarrow \mathrm{GL}(V).$$

**Remark 3.14.** For local fields  $k$ , such as  $k \in \{\mathbb{R}, \mathbb{C}, \mathbb{Q}_p\}$ , the situation is more straightforward in the following sense. If  $X \hookrightarrow Y$  is an open immersion of  $k$ -varieties, then  $X(k) \rightarrow Y(k)$  is an open immersion with respect to the topologies from Definition 3.8. In particular, the topology on  $X(k)$  from Definition 3.8 agrees with the subspace topology in  $Y(k)$ .

This remark applies, for example, to

$$\mathrm{GL}_n(\mathbb{R}) \subset \mathrm{M}_n(\mathbb{R}) \quad \text{and} \quad \mathrm{GL}_n(\mathbb{Q}_p) \subset \mathrm{M}_n(\mathbb{Q}_p).$$

**3.3. General adelic double quotients.** Let us begin with a general theorem which we will not prove.

**Theorem 3.15** ([12, Theorem 4.16]). (1) Let  $G/\mathbb{Q}$  be a connected reductive algebraic group. Then, for every compact open subgroup  $K \subset G(\mathbb{A}_f)$ , the double quotient  $G(\mathbb{Q}) \backslash G(\mathbb{A}_f) / K$  is finite.

(2, Strong approximation) Let  $G/\mathbb{Q}$  be a connected, simply connected semi-simple group of non-compact type. Then  $G(\mathbb{Q})$  is dense in  $G(\mathbb{A}_f)$ . In particular, for every compact open subgroup  $K \subset G(\mathbb{A}_f)$ ,

$$G(\mathbb{A}_f) = \{\gamma \cdot k \mid \gamma \in G(\mathbb{Q}), k \in K\}.$$

As our first application, we obtain a more concrete description of the adelic double quotients that make up the complex points of a Shimura variety (1.6). Let  $(G, X)$  be a Shimura datum and let  $K \subset G(\mathbb{A}_f)$  be a level subgroup. In particular,  $G$  is a connected reductive group over  $\mathbb{Q}$ , so Theorem 3.15 (1) applies. So we find finitely many double coset representatives  $g_1, \dots, g_r \in G(\mathbb{A}_f)$ ,

$$G(\mathbb{A}_f) = \bigsqcup_{i=1}^r G(\mathbb{Q})g_iK. \quad (3.8)$$

Each of the sets on the right hand side of (3.8) is  $G(\mathbb{Q})$ -stable. Moreover,  $G(\mathbb{Q})$  acts transitively on the cosets  $G(\mathbb{Q})g_iK/K$ , and the stabilizer of the coset  $g_iK \in G(\mathbb{Q})g_iK/K$  is the subgroup

$$\Gamma_i := G(\mathbb{Q}) \cap g_iKg_i^{-1}.$$

So we obtain

$$\begin{aligned} G(\mathbb{Q}) \backslash (X \times G(\mathbb{A}_f)/K) &= \bigsqcup_{i=1}^r G(\mathbb{Q}) \backslash (X \times G(\mathbb{Q})g_iK/K) \\ &\xrightarrow{\sim} \bigsqcup_{i=1}^r \Gamma_i \backslash X \times \{g_iK\}. \end{aligned} \quad (3.9)$$

If  $K$  is small enough, which we will make precise for  $\mathrm{GL}_2$  in a minute, then each  $\Gamma_i$  is torsion-free and acts without stabilizers on  $X$ . Each quotient  $\Gamma_i \backslash X$  is then a complex manifold in the same way as we saw before in Conclusion 2.11.

**Exercise 3.16.** Work out (3.9) for yourself. For example, first prove the following variant. Let  $H$  be a group acting on sets  $X$  and  $Y$ . Let  $Y = \sqcup_{i \in I} G \cdot y_i$  be the decomposition of  $Y$  into orbits and let  $\Gamma_i$  be the stabilizer of  $y_i$  in  $H$ . Then

$$H \backslash (X \times Y) \xrightarrow{\sim} \bigsqcup_{i \in I} \Gamma_i \backslash X.$$

Specialize to the situation  $H = G(\mathbb{Q})$  and  $Y = G(\mathbb{A}_f)/K$ .

**Exercise 3.17.** The group  $\mathrm{SL}_n$  is connected, simply connected, semi-simple and of non-compact type, so  $\mathrm{SL}_n(\mathbb{Q}) \subset \mathrm{SL}_n(\mathbb{A}_f)$  is dense (Strong approximation, see Theorem 3.15 (2)). Using this property, show that

$$\mathrm{SL}_n(\mathbb{Z}) \longrightarrow \mathrm{SL}_n(\mathbb{Z}/m\mathbb{Z})$$

is surjective for all  $m \geq 1$ . In particular, this shows the surjectivity of (2.5).

**3.4. Back to  $\mathrm{GL}_2$ .** The description in (3.9) is still quite abstract. We now want to make it completely explicit for congruence subgroups of  $\mathrm{GL}_2$ . Let us begin by studying  $\mathbb{G}_m$ .

**Proposition 3.18.** *Let  $K(m) = \ker(\widehat{\mathbb{Z}}^\times \rightarrow (\mathbb{Z}/m\mathbb{Z})^\times)$  be the  $m$ -th congruence subgroup of  $\mathbb{A}_f^\times$ . Then there is an isomorphism*

$$\mathbb{Q}_{>0}^\times \backslash \mathbb{A}_f^\times / K(m) \xrightarrow{\sim} (\mathbb{Z}/m\mathbb{Z})^\times. \quad (3.10)$$

*Proof.* Let  $x = (x_p)_p \in \mathbb{A}_f^\times$  be an element. Here, the component  $x_p$  lies in  $\mathbb{Q}_p^\times$ , and almost all components  $x_p$  even lie in  $\mathbb{Z}_p^\times$ . For each prime  $p$ , let  $v_p : \mathbb{Q}_p^\times \rightarrow \mathbb{Z}$  denote the valuation normalized by  $v_p(p) = 1$ . Take the vector of valuations of all the entries of  $x$ :

$$(e_p)_p, \quad e_p = v_p(x_p).$$

Only finitely many of the  $e_p$  are non-zero. There is a rational number in  $\mathbb{Q}_{>0}$  with the same valuations, namely  $t = \prod_p p^{e_p}$ . So  $t^{-1}x$  lies in  $\widehat{\mathbb{Z}}^\times$  which shows that every double coset in (3.10) has a representative in  $\widehat{\mathbb{Z}}^\times$ . Purely formally, we now obtain

$$\mathbb{Q}_{>0}^\times \backslash \mathbb{A}_f^\times / K(m) \xrightarrow{\sim} (\mathbb{Q}_{>0}^\times \cap \widehat{\mathbb{Z}}^\times) \backslash \widehat{\mathbb{Z}}^\times / K(m). \quad (3.11)$$

The rational number  $t$  is, in fact, uniquely determined which reflects that  $\mathbb{Q}_{>0}^\times \cap \widehat{\mathbb{Z}}^\times = \{1\}$ . So (3.11) simplifies to  $\widehat{\mathbb{Z}}^\times / K(m)$ , which is isomorphic to  $(\mathbb{Z}/m\mathbb{Z})^\times$  as claimed.  $\square$

We write  $\mathrm{GL}_n(\mathbb{Q})_{>0}$  for the subgroup of elements of  $\mathrm{GL}_n(\mathbb{Q})$  with positive determinant.

**Proposition 3.19.** *Let  $K \subset \mathrm{GL}_n(\mathbb{A}_f)$  be an open compact subgroup. The determinant map  $\det : \mathrm{GL}_n(\mathbb{A}_f) \rightarrow \mathbb{A}_f^\times$  induces a bijection*

$$\det : \mathrm{GL}_n(\mathbb{Q})_{>0} \backslash \mathrm{GL}_n(\mathbb{A}_f) / K \xrightarrow{\sim} \mathbb{Q}_{>0}^\times \backslash \mathbb{A}_f^\times / \det(K). \quad (3.12)$$

*Proof.* The group  $\mathrm{SL}_n$  is connected, simply connected, semi-simple and of non-compact type, so  $\mathrm{SL}_n(\mathbb{Q}) \subset \mathrm{SL}_n(\mathbb{A}_f)$  is dense (Strong approximation, see Theorem 3.15 (2)). We will use this property freely.

Consider the determinant map in (3.12). It is clearly surjective because already the map  $\det : \mathrm{GL}_n(\mathbb{A}_f) \rightarrow \mathbb{A}_f^\times$  is surjective. So our task is to prove that (3.12) is injective.

The source in (3.12) is only a set, so we cannot argue with kernels. Instead, we consider two elements  $g_1, g_2 \in \mathrm{GL}_n(\mathbb{A}_f)$  with the same image, meaning that

$$\det(g_1) \in \mathbb{Q}_{>0}^\times \det(g_2) \det(K). \quad (3.13)$$

Our task is to show that  $g_1 \in \mathrm{GL}_n(\mathbb{Q})g_2K$ .

First, observe that  $\det : \mathrm{GL}_n(\mathbb{Q})_{>0} \rightarrow \mathbb{Q}_{>0}^\times$  is surjective. So we find elements  $h \in \mathrm{GL}_n(\mathbb{Q})_{>0}$  and  $k \in K$  such that  $\det(g_1) = \det(hg_2k)$ . So after replacing  $g_2$  by  $hg_2k$ , we may assume  $\det(g_1) = \det(g_2)$ .

Next, we consider the conjugate group  $g_2Kg_2^{-1}$ . Strong approximation for  $\mathrm{SL}_n$  implies that

$$\mathrm{SL}_n(\mathbb{A}_f) = \mathrm{SL}_n(\mathbb{Q}) \cdot (g_2Kg_2^{-1} \cap \mathrm{SL}_n(\mathbb{A}_f)).$$

Hence, there are  $h' \in \mathrm{SL}_n(\mathbb{Q})$  and  $k' \in K \cap \mathrm{SL}_n(\mathbb{A}_f)$  with

$$g_1g_2^{-1} = h'g_2k'g_2^{-1}.$$

This is equivalent to  $g_1 = h'g_2k'$ , showing that the double cosets of  $g_1$  and  $g_2$  are equal as claimed.  $\square$

**Corollary 3.20.** *Let  $K(m) \subset \mathrm{GL}_2(\mathbb{A}_f)$  be the  $m$ -th congruence subgroup. There is a bijection of connected components*

$$\pi_0(\mathrm{GL}_2(\mathbb{Q}) \backslash (\mathbb{H}^\pm \times \mathrm{GL}_2(\mathbb{A}_f) / K(m))) \xrightarrow{\sim} (\mathbb{Z}/m\mathbb{Z})^\times. \quad (3.14)$$

*Moreover, the connected components are all of the form  $\Gamma \backslash \mathbb{H}$  with  $\Gamma = \mathrm{GL}_2(\mathbb{Q})_{>0} \cap gK(m)g^{-1}$  for some element  $g \in \mathrm{GL}_2(\mathbb{A}_f)$ .*

*Proof.* The two connected components of  $\mathbb{H}^\pm$  are interchanged by the elements of negative determinant in  $\mathrm{GL}_2(\mathbb{Q})$ . Hence, we obtain

$$\begin{aligned} \pi_0(\mathrm{GL}_2(\mathbb{Q}) \backslash (\mathbb{H}^\pm \times \mathrm{GL}_2(\mathbb{A}_f) / K(m))) &\xrightarrow{\sim} \pi_0(\mathrm{GL}_2(\mathbb{Q})_{>0} \backslash (\mathbb{H} \times \mathrm{GL}_2(\mathbb{A}_f) / K(m))) \\ &\xrightarrow{\sim} \mathrm{GL}_2(\mathbb{Q})_{>0} \backslash \mathrm{GL}_2(\mathbb{A}_f) / K(m). \end{aligned} \quad (3.15)$$

Here, the second isomorphism simply used that  $\mathbb{H}$  is connected. Next, observe that

$$L := \det(K(m)) = \ker(\widehat{\mathbb{Z}}^\times \rightarrow (\mathbb{Z}/m\mathbb{Z})^\times)$$

is the  $m$ -th congruence subgroup in  $\mathbb{A}_f^\times$ . So, by Proposition 3.19, the determinant allows to rewrite (3.15) as

$$\det : \mathrm{GL}_2(\mathbb{Q})_{>0} \backslash \mathrm{GL}_2(\mathbb{A}_f) / K(m) \xrightarrow{\sim} \mathbb{Q}_{>0}^\times \backslash \mathbb{A}_f^\times / L.$$

By Proposition 3.18, the last expression can be identified with  $(\mathbb{Z}/m\mathbb{Z})^\times$  as claimed.

The final statement (each connected component being isomorphic to some  $\Gamma \backslash \mathbb{H}$  with  $\Gamma$  of the form  $\mathrm{GL}_2(\mathbb{Q})_{>0} \cap gK(m)g^{-1}$ ) is a special case of the decomposition in (3.9), except that we have already replaced  $(\mathbb{H}^\pm, \mathrm{GL}_2(\mathbb{Q}))$  by  $(\mathbb{H}, \mathrm{GL}_2(\mathbb{Q})_{>0})$ .  $\square$

Let us go further and prove a criterion that ensures that all the occurring  $\Gamma$  are torsion free. The arguments will be similar to the ones we saw in §2.3.

**Proposition 3.21.** *For any  $m \geq 3$  and  $g \in \mathrm{GL}_2(\mathbb{A}_f)$ , the intersection  $\Gamma = \mathrm{GL}_2(\mathbb{Q}) \cap gK(m)g^{-1}$  is torsion free.*

*Proof.* Let  $\gamma$  be an element of  $K(m)$ . Then, since  $K(m) \subseteq \mathrm{GL}_2(\widehat{\mathbb{Z}})$ , the characteristic polynomial  $P_\gamma(T)$  lies in  $\widehat{\mathbb{Z}}[T]$ . Since  $\gamma \equiv 1 \pmod{m}$ , we even know  $P_\gamma(T) \equiv (T-1)^2 \pmod{m}$ . In general, for every  $n \geq 1$  and any ring  $R$ , the characteristic polynomial of an element from  $\mathrm{GL}_n(R)$  is invariant under conjugation. So, in our setting, the same properties hold for  $P_\gamma(T)$  for  $\gamma \in gK(m)g^{-1}$ .

Assume that  $\gamma \in \Gamma = \mathrm{GL}_2(\mathbb{Q}) \cap gK(m)g^{-1}$ . Then, the characteristic polynomial of  $\gamma$  has rational coefficients, and hence lies in the intersection

$$\mathbb{Q}[T] \cap ((T-1)^2 + n\widehat{\mathbb{Z}}[T]).$$

This means that  $P_\gamma(T) \in \mathbb{Z}[T]$  and  $P_\gamma(T) \equiv (T-1)^2 \pmod{m}$ .

If  $\gamma$  is a torsion element, then we have already seen during the proof of Proposition 2.9 that  $P_\gamma(T)$  comes from the list (2.7). By the congruence condition we just established, the only possibility is  $P_\gamma(T) = (T-1)^2$ . The matrix  $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$  is not torsion, so cannot be the Jordan normal form of  $\gamma$ . We conclude that  $\gamma = 1$ , showing that  $\Gamma$  is torsion-free as claimed.  $\square$

**Conclusion 3.22.** Let us come back to the situation of Corollary 3.20. Assume that  $m \geq 3$ . Then the connected components of

$$\mathrm{GL}_2(\mathbb{Q}) \backslash (\mathbb{H}^\pm \times \mathrm{GL}_2(\mathbb{A}_f))$$

are in natural bijection with  $(\mathbb{Z}/m\mathbb{Z})^\times$ . Each connected component is of the form  $\Gamma \backslash \mathbb{H}$  for a torsion free arithmetic subgroup  $\Gamma \subseteq \mathrm{SL}_2(\mathbb{Q})$ .

## 4. GROUP SCHEMES

Our next aim is to endow the complex manifolds  $\mathrm{Sh}_K(\mathrm{GL}_2, \mathbb{H}^\pm)(\mathbb{C})$  with an algebraic structure and to even define them over  $\mathbb{Q}$  (see 1.7). This relies on their description as moduli spaces of elliptic curves:

**Definition 4.1.** Let  $k$  be a field. An *elliptic curve* over  $k$  is a proper, smooth, connected and 1-dimensional  $k$ -group scheme.

Later in the course, we will also consider other Shimura varieties and describe them as moduli spaces of abelian varieties:

**Definition 4.2.** An *abelian variety* over  $k$  is a proper, smooth and connected  $k$ -group scheme.

In this lecture, we will first discuss some background on group schemes. This will also be useful for talking about groups like  $\mathrm{GL}_n$ ,  $\mathrm{GSp}_{2g}$  etc. which we have secretly already considered as group schemes over  $\mathrm{Spec} \mathbb{Z}$  or  $\mathrm{Spec} \mathbb{Q}$  in previous lectures. In general, group schemes are also an interesting topic in itself and come up in many areas of algebra.

**Recommended reading closely related to our course:** My lecture notes on moduli spaces of elliptic curves [9]. Parts of our discussion here are taken from [9, §2].

**General reference on algebraic groups:** Milne's book [13], especially §1 about basic definitions.

**4.1. Basic definitions.** We give the definition over a general base  $S$ , but the case to keep in mind is  $S = \mathrm{Spec}(k)$  for a field  $k$ .

**Definition 4.3.** Let  $S$  be a scheme. A *group scheme* over  $S$  is a pair  $(G, m)$  that consists of an  $S$ -scheme  $G$  and an  $S$ -scheme morphism (called multiplication morphism)

$$m : G \times_S G \longrightarrow G$$

such that for every  $S$ -scheme  $T$ , the resulting map on  $T$ -valued points

$$m(T) : G(T) \times G(T) \longrightarrow G(T)$$

makes  $G(T)$  into a group. We call  $G$  *commutative* if  $G(T)$  is a commutative group for every  $T$ .

Observe that for every morphism  $u : T' \rightarrow T$  of  $S$ -schemes, the diagram

$$\begin{array}{ccc} G(T) \times G(T) & \xrightarrow{m(T)} & G(T) \\ u^* \times u^* \downarrow & & \downarrow u^* \\ G(T') \times G(T') & \xrightarrow{m(T')} & G(T') \end{array} \quad (4.1)$$

commutes which means that  $u^* : G(T) \rightarrow G(T')$  is a group homomorphism. Furthermore, if  $(G, m)$  is a group scheme over  $S$ , then the Yoneda Lemma implies the existence of two additional  $S$ -scheme morphisms:

$$\begin{aligned} e : S &\longrightarrow G, & (\text{neutral element section}) \\ i : G &\longrightarrow G, & (\text{inversion morphism}). \end{aligned} \quad (4.2)$$

The first one is simply the neutral element  $e \in G(S)$  of the group  $G(S)$ . Given  $u : T \rightarrow S$ , the pullback  $u^*(e) = e \circ u \in G(T)$  is the neutral element of  $G(T)$ . The second one is characterized as the unique morphism that provides the inverse in all the groups  $\{G(T)\}_{T \rightarrow S}$ :

$$i(T) : G(T) \longrightarrow G(T), \quad g \longmapsto g^{-1}.$$

The datum  $(G, m, e, i)$  satisfies the group axioms in a scheme sense, meaning that the three diagrams

$$\begin{array}{ccc} S \times_S G & \xrightarrow{e \times \text{id}} & G \times_S G \\ & \searrow & \swarrow m \\ & G, & \end{array} \quad (4.3)$$

$$\begin{array}{ccc} G \times_S G & \xrightarrow{\text{id} \times i} & G \times_S G \\ \downarrow & & \downarrow m \\ S & \xrightarrow{e} & G, \end{array} \quad \begin{array}{ccc} G \times_S G \times_S G & \xrightarrow{m \times \text{id}} & G \times_S G \\ \text{id} \times m \downarrow & & \downarrow m \\ G \times_S G & \xrightarrow{m} & G. \end{array} \quad (4.4)$$

all commute. In fact, one may also reverse the above logic and obtains the more classical definition of a group scheme over  $S$ : It is the same as an  $S$ -scheme  $G$  together with a morphism  $m : G \times_S G \rightarrow G$  such that there exist morphisms  $e : S \rightarrow G$  and  $i : G \rightarrow G$  such that the diagrams in (4.3) and (4.4) commute. The group scheme  $(G, m)$  is commutative if and only if multiplication interchanges with switching the factors in the sense that also the following diagram commutes:

$$\begin{array}{ccc} G \times_S G & \xrightarrow{(g,h) \mapsto (h,g)} & G \times_S G \\ & \searrow m & \swarrow m \\ & G. & \end{array} \quad (4.5)$$

**Definition 4.4.** Let  $(G_1, m_1)$  and  $(G_2, m_2)$  be group schemes over  $S$ . A group scheme morphism from  $G_1$  to  $G_2$  is a morphism of  $S$ -schemes  $f : G_1 \rightarrow G_2$  such that  $m_2 \circ (f \times f) = f \circ m_1$ . Equivalently, it is an  $S$ -morphism  $f$  such that for all  $T \rightarrow S$ , the induced map

$$f(T) : G_1(T) \longrightarrow G_2(T)$$

is a group homomorphism.

If  $(G, m)$  is a *commutative*  $S$ -group scheme, then  $\text{End}_{S\text{-Grp.Sch.}}(G, m)$  forms a (possibly non-commutative) ring because endomorphisms can be “added” (meaning multiplied in  $G$ ) and multiplied (meaning composed). Concretely, sum and product of two elements  $f, g \in \text{End}(G)$  are given by

$$f + g := m \circ (f, g), \quad fg := f \circ g.$$

In particular, we can add the identity  $n$  times to itself and obtain the  $n$ -th power endomorphism  $[n] : G \rightarrow G$ . On each of the groups  $G(T)$ , it is given by  $[n](g) = g^n$ . This is even defined for  $n \in \mathbb{Z}$  by  $[n] \circ i = [-n]$ . In total, these give the ring map

$$[\cdot] : \mathbb{Z} \rightarrow \text{End}(G). \quad (4.6)$$

Coming back to general group schemes, we next define kernels. This is straightforward because fiber products exist in the category of  $S$ -schemes. (Defining quotients, on the other hand, is tricky. We refer to [9, §13] for some cases.)

**Definition 4.5.** Let  $f : G_1 \rightarrow G_2$  be a homomorphism of  $S$ -group schemes. Let  $e_2 : S \rightarrow G_2$  be the neutral element section of  $G_2$ . The kernel of  $f$  is defined as the fiber product

$$\begin{array}{ccc} \ker(f) & \longrightarrow & S \\ \downarrow & & \downarrow e_2 \\ G_1 & \xrightarrow{f} & G_2. \end{array} \quad (4.7)$$

It is clear from its definition that  $\ker(f)$  has the property

$$\ker(f)(T) = \ker(f(T) : G_1(T) \longrightarrow G_2(T)). \quad (4.8)$$

The multiplication morphism of  $G_1$  restricts to a multiplication on  $\ker(f)$  which makes  $\ker(f)$  into a group scheme:

$$\begin{array}{ccc} \ker(f) \times_S \ker(f) & \xrightarrow{\quad m \quad} & \ker(f) \\ \downarrow & & \downarrow \\ G \times_S G & \xrightarrow{\quad m \quad} & G. \end{array} \quad (4.9)$$

**Remark 4.6.** Recall that if  $X \rightarrow S$  is a separated morphism, then every section  $\sigma : S \rightarrow X$  is a closed immersion. Thus, if  $G \rightarrow S$  is a separated group scheme (e.g. affine or proper), then the neutral element  $e$  is a closed immersion. It follows that if in (4.7)  $G_2 \rightarrow S$  is separated, then  $\ker(f) \rightarrow G_1$  is a closed immersion.

**4.2. A commutative example: The multiplicative group.** Assume that  $S = \operatorname{Spec} R$  is affine. Define  $\mathbb{G}_{m,S} = \operatorname{Spec} R[t, t^{-1}]$  which we would like to make into a group scheme over  $S$ . Recall that  $\operatorname{Spec}(-)$  is an anti-equivalence from  $R$ -algebras to affine  $S$ -schemes. We define the multiplication map  $m : \mathbb{G}_{m,S} \times_S \mathbb{G}_{m,S} \rightarrow \mathbb{G}_{m,S}$  as  $\operatorname{Spec}(m^*)$  where  $m^*$  is

$$\begin{aligned} m^* : R[t, t^{-1}] &\longrightarrow R[t, t^{-1}] \otimes_R R[t, t^{-1}] \\ t &\longmapsto t \otimes t. \end{aligned} \quad (4.10)$$

We next verify that this makes  $\mathbb{G}_{m,S}$  into an  $S$ -group scheme. For every  $S$ -scheme  $T$ , we identify

$$\begin{aligned} \mathbb{G}_{m,S}(T) &\xrightarrow{\sim} \mathcal{O}_T(T)^\times \\ [g : T \rightarrow \mathbb{G}_{m,S}] &\longmapsto g^*(t). \end{aligned} \quad (4.11)$$

Note that this map is obviously defined; the fact that it is an isomorphism is the adjunction  $\operatorname{Mor}_S(T, \operatorname{Spec}(A)) \xrightarrow{\sim} \operatorname{Hom}_R(A, \mathcal{O}_T(T))$ . Given two morphisms  $g_1, g_2 : T \rightarrow \mathbb{G}_{m,S}$ , we compute the (dual of the) composition  $m \circ (g_1, g_2)$  by

$$\begin{aligned} R[t, t^{-1}] &\xrightarrow{m^*} R[t, t^{-1}] \otimes_R R[t, t^{-1}] \xrightarrow{g_1^* \otimes g_2^*} \mathcal{O}_T(T) \\ t &\longmapsto t \otimes t \longmapsto g_1^*(t)g_2^*(t). \end{aligned}$$

Thus we see that the operation  $m(T)$  on  $\mathbb{G}_{m,S}(T)$  translates to the usual multiplication under (4.11). In particular,  $m(T)$  is a group structure for every  $T$ , and hence  $(\mathbb{G}_{m,S}, m)$  a group scheme.

We can next calculate the neutral element  $e$  and the inversion map  $i$  from (4.2). Under (4.11), the unit element  $1 \in R^\times$  corresponds to

$$e^* : R[t, t^{-1}] \longrightarrow R, \quad t \longmapsto 1.$$

Taking  $e = \operatorname{Spec}(e^*)$  gives the neutral element section. The inversion map  $i = \operatorname{Spec}(i^*)$  is given by

$$i^* : R[t, t^{-1}] \longrightarrow R[t, t^{-1}], \quad t \longmapsto t^{-1}. \quad (4.12)$$

The  $n$ -th power maps are given as  $[n] = \operatorname{Spec}([n]^*)$  with

$$[n]^* : R[t, t^{-1}] \longrightarrow R[t, t^{-1}], \quad t \longmapsto t^n. \quad (4.13)$$

Note that (4.12) and (4.13) are compatible in the sense that  $i = [-1]$ , which is always the case for a commutative group scheme. The next proposition, on the other hand, is very specific to  $\mathbb{G}_m$ .

**Proposition 4.7.** *Let  $S$  be a connected scheme. Then  $\operatorname{End}(\mathbb{G}_{m,S}) = \mathbb{Z}$ .*

*Proof.* We only consider the case  $S = \operatorname{Spec}(k)$ . The extension to general  $S$  can be found in [9, Proposition 2.12].

By definition, a group scheme endomorphism  $f$  of  $\mathbb{G}_{m,k}$  is the same as  $f = \operatorname{Spec}(f^*)$  for a unique  $k$ -algebra morphism  $f^* : k[t, t^{-1}] \rightarrow k[t, t^{-1}]$  such that

$$(f^* \otimes f^*) \circ m^* = m^* \circ f^* \quad (4.14)$$

where  $m^*(t) = t \otimes t$  is as in (4.10). Giving a  $k$ -algebra morphism  $f^*$  is equivalent to specifying its image  $f^*(t) \in k[t, t^{-1}]^\times$ . These units are

$$k[t, t^{-1}]^\times = \{\lambda t^n \mid \lambda \in k^\times, n \in \mathbb{Z}\}.$$

If  $f^*(t) = \lambda t^n$ , then (4.14) evaluated at  $t$  becomes

$$\lambda t^n \otimes \lambda t^n \stackrel{?}{=} \lambda(t \otimes t)^n \quad (4.15)$$

which holds if and only if  $\lambda^2 = \lambda$ , meaning  $\lambda = 1$ . Note that  $f^*(t) = t^n$  precisely defines the multiplication-by- $n$  morphism  $[n]$  (meaning taking  $n$ -th power in this context) and thus  $\operatorname{End}(\mathbb{G}_{m,k}) = \mathbb{Z}$  is proved.  $\square$

We next determine the kernel  $\mu_{n,S} := \ker([n])$ . By definition, see (4.7), we need to compute the fiber product

$$\begin{array}{ccc} \mu_{n,S} & \longrightarrow & S \\ \downarrow & & \downarrow \\ \mathbb{G}_{m,S} & \xrightarrow{[n]} & \mathbb{G}_{m,S}. \end{array}$$

Fiber products of affine schemes are computed by tensor products of rings, so we get

$$\begin{aligned} \mu_{n,S} &= \operatorname{Spec}(R \otimes_{1 \leftarrow t, R[t, t^{-1}], t \mapsto t^n} R[t, t^{-1}]) \\ &= \operatorname{Spec}(R[t]/(t^n - 1)). \end{aligned} \quad (4.16)$$

In terms of (4.8) and (4.11), we see

$$\mu_{n,S}(T) = \{\zeta \in \mathcal{O}_T(T)^\times \mid \zeta^n = 1\}. \quad (4.17)$$

That is,  $\mu_{n,S}$  is the *group scheme of  $n$ -th roots of unity*. Let us assume that  $S = \operatorname{Spec}(k)$ . We observe the following interesting phenomenon:

Assume that  $n$  is prime to  $\operatorname{char}(k)$ . Then  $t^n - 1 \in k[t]$  is a separable polynomial. Hence,  $\mu_{n,k} = \operatorname{Spec} k[t]/(t^n - 1)$  is an étale  $k$ -scheme. On the other hand, if  $p = \operatorname{char}(k) \mid n$ , then  $t^n - 1$  is not separable and  $k[t]/(t^n - 1)$  is not reduced. For example,

$$\begin{aligned} \mu_{p,k} &= \operatorname{Spec} k[t]/(t^p - 1) \\ &= \operatorname{Spec} k[t]/(t - 1)^p \\ &\xrightarrow{\sim} \operatorname{Spec} k[\varepsilon]/(\varepsilon^p) \end{aligned}$$

is completely infinitesimal. We have the following general results in this direction.

**Theorem 4.8** (Cartier, [13, Corollary 8.38]). *Let  $k$  be a field of characteristic 0 and let  $G/k$  be a finite type group scheme. Then  $G$  is smooth.*

A morphism  $f : X \rightarrow S$  is said to be *finite locally free of rank  $n$*  if it is finite and if  $f_*(\mathcal{O}_X)$  is locally free of rank  $n$  as  $\mathcal{O}_S$ -module.

**Theorem 4.9.** *Let  $G$  be a commutative  $S$ -group scheme which is finite locally free of rank  $n$ . Assume that  $n \in \mathcal{O}_S(S)^\times$ . Then  $G$  is étale.*

**Exercise 4.10.** Verify the commutativity of (4.3) and (4.4) for  $(\mathbb{G}_m, m, e, i)$ .

**4.3. A non-commutative example:  $\mathrm{GL}_n$ .** Let  $S = \mathrm{Spec}(R)$  be affine as before. The (underlying scheme of the) general linear group in  $n$  variables over  $S$  is defined as

$$\mathrm{GL}_{n,S} = \mathrm{Spec} R[t_{ij}, 1 \leq i, j \leq n; \det((t_{ij})_{i,j})^{-1}].$$

For every  $S$ -scheme  $T$ , we can (exercise) identify  $\mathrm{GL}_{n,S}(T)$  with  $\mathrm{GL}_n(\mathcal{O}_T(T))$  by

$$\Phi : [g : T \rightarrow \mathrm{GL}_{n,S}] \mapsto (g^*(t_{ij}))_{i,j}. \quad (4.18)$$

We have the usual matrix multiplication on  $\mathrm{GL}_n(\mathcal{O}_T(T))$ . In terms of (4.18), it comes from the multiplication morphism  $m : \mathrm{GL}_{n,S} \times_S \mathrm{GL}_{n,S} \rightarrow \mathrm{GL}_{n,S}$  which is given in coordinates by

$$m^*(t_{ij}) = \sum_{k=1}^n t_{ik} \otimes t_{kj}.$$

The pair  $(\mathrm{GL}_{n,S}, m)$  is then an  $S$ -group scheme. The identity map  $e = \mathrm{Spec}(e^*)$  is given by

$$e^* : R[t_{ij}, \det((t_{ij})_{i,j})^{-1}] \longrightarrow R, \quad e^*(t_{ij}) = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{otherwise.} \end{cases}$$

The inverse of the matrix  $(t_{ij})_{i,j} \in \mathrm{GL}_n(R[t_{ij}, \det((t_{ij})_{i,j})^{-1}])$  has an expression of the form  $\det((t_{ij})_{i,j})^{-1} \cdot (s_{ij})_{i,j}$  where the  $s_{ij}$  are polynomials in the variables  $t_{ij}$ . (In fact, the  $s_{ij}$  are the entries of the adjugate matrix.) Then the inverse morphism  $i : \mathrm{GL}_{n,S} \rightarrow \mathrm{GL}_{n,S}$  is given in coordinates by

$$i^*(t_{kl}) = \det((t_{ij})_{i,j})^{-1} s_{kl}.$$

Clearly,  $\mathrm{GL}_{1,S}$  is the same as the multiplicative group  $\mathbb{G}_{m,S}$ . For every  $S$ -scheme  $T$ , we have a determinant morphism  $\mathrm{GL}_n(\mathcal{O}_T(T)) \rightarrow \mathcal{O}_T(T)^\times$ . With respect to our identifications (4.11) and (4.18), these come from the group scheme homomorphism

$$\det : \mathrm{GL}_{n,S} \longrightarrow \mathbb{G}_{m,S}, \quad \det^*(t) = \det((t_{ij})_{i,j}). \quad (4.19)$$

Its kernel  $\ker(\det)$  is the group subscheme  $\mathrm{SL}_{n,S} \subset \mathrm{GL}_{n,S}$ . Being a closed subscheme of an affine scheme, it is again affine. It can be described explicitly by

$$\mathrm{SL}_{n,S} = \mathrm{Spec} (R[t_{ij}, 1 \leq i, j \leq n] / (\det((t_{ij})_{i,j}) - 1)).$$

**4.4. Linear algebraic groups.** We now specialize to the case of finite type group schemes over a field  $k$ . A general classification theorem essentially reduces their study to the affine and the proper case.

**Theorem 4.11** (see [13, §8a]). *Let  $G/k$  be a connected finite type  $k$ -group scheme. Then there exists a unique maximal normal, connected, affine closed group sub-scheme  $N \subseteq G$ . The quotient  $G/N$  is an abelian variety.*

Affine finite type  $k$ -group schemes are also called *linear algebraic groups*. The reason for this name is that they can always be realized as a group of linear automorphisms of some vector space. That is, they always embed into some  $\mathrm{GL}_N$ .

**Theorem 4.12** (see [13, Corollary 4.10]). *Let  $G$  be an affine finite type  $k$ -group scheme. Then there exist an integer  $n$  and a closed immersion group scheme morphism  $G \rightarrow \mathrm{GL}_n$ .*

**4.5. Abelian varieties.** We have already defined abelian varieties in Definition 4.2. The main point of this definition is that abelian varieties are proper. This implies that they are necessarily commutative which also explains their name.

**Theorem 4.13** ([9, Corollary 3.7]). *Let  $(A, m)$  be an abelian variety over  $k$ . Then  $(A, m)$  is a commutative group scheme.*

## 5. ELLIPTIC CURVES

In the previous section, we defined elliptic curves as proper, smooth, 1-dimensional, connected group schemes and stated that they are always commutative (Definition 4.1 and Theorem 4.13). However, this definition does not shed any light on how to actually write down even a single elliptic curve. Fortunately, there are two equivalent characterizations:

- An elliptic curve over a field  $k$  is a pair  $(E, e)$  consisting of a proper smooth connected curve  $E/k$  of genus 1 and a rational point  $e \in E(k)$ .
- An elliptic curve over a field  $k$  is a smooth cubic curve  $E \subset \mathbb{P}_k^2$  that contains the point  $[0 : 1 : 0]$ .

In today's lecture, we want to learn how to pass between the three definitions. There is, actually, a lot to say about this, and a detailed treatment would touch upon many concepts in algebraic geometry. These details can all be found in [9, §4 – §7], but some of them are tangential for our course. So we will give a shorter and more high-level discussion.

**5.1. Cubic curves are elliptic curves.** Our first aim is to construct elliptic curves. Let  $h(x) = x^3 + ax + b$  be a monic cubic polynomial (without  $x^2$ -term). A polynomial of the form

$$f = y^2 - h(x) \tag{5.1}$$

is called a *simplified Weierstrass equation*. Let

$$F(X, Y, Z) = Y^2Z - X^3 - aXZ^2 - bZ^3 \tag{5.2}$$

be the homogenization of  $f$ , and let  $E = V_+(F) \subset \mathbb{P}_k^2$  be its vanishing locus.

**Lemma 5.1.** *Assume that  $\text{char}(k) \neq 2$  and that  $h$  is separable. Then  $E$  is a smooth curve.*

*Proof.* First observe by direct substitution in (5.2) that  $E \cap V_+(Z) = \{[0 : 1 : 0]\}$ . Thus we can proceed by checking the Jacobi criterion on  $E \cap D_+(Z)$  and for the point  $[0 : 1 : 0]$ .

By definition, we have

$$E \cap D_+(Z) \xrightarrow{\sim} V(y^2 - h(x)) \subset \mathbb{A}_k^2.$$

The Jacobi matrix of the Weierstrass polynomial is the gradient

$$(\partial f / \partial x, \partial f / \partial y) = (-h'(x), 2y). \tag{5.3}$$

Let  $e \in E \cap D_+(Z)$  be an arbitrary point. Let  $\kappa(e)$  be the residue field of  $e$  and let  $(e_1, e_2) \in \kappa(e) \times \kappa(e)$  be the coordinates of  $e$ .<sup>5</sup> If  $e_2 \neq 0$ , then also  $2e_2 \neq 0$  by our assumption  $\text{char}(k) \neq 2$ , meaning  $2y$  does not vanish in  $e$ . If  $e_2 = 0$ , however, then  $h(e_1) = 0$  since  $f(e_1, e_2) = 0$ . We have assumed that  $h$  is separable, which is equivalent to  $h(x)$  and  $h'(x)$  being coprime. Thus  $h'(e_1) \neq 0$ . In summary, we have seen that the gradient (5.3) does not vanish in  $e$ .

We now consider the point  $[0 : 1 : 0]$ . An affine chart is given by

$$E \cap D_+(Y) \xrightarrow{\sim} V(z - x^3 - axz^2 - bz^3) \subset \mathbb{A}_k^2.$$

In these coordinates,  $[0 : 1 : 0]$  maps to  $(0, 0)$ . Moreover, the gradient of that equation is

$$(-3x^2 - az^2, 1 - 2axz - bz^2). \tag{5.4}$$

Its second entry does not vanish in  $(0, 0)$ , so the Jacobi criterion holds in  $(0, 0)$ . The proof of the lemma is now complete.  $\square$

**Theorem 5.2.** *Let  $E = V_+(F) \subset \mathbb{P}_k^2$  be a smooth cubic curve, and let  $O \in E(k)$  be a rational point. Then there exists a unique group scheme structure  $+: E \times_{\text{Spec}(k)} E \rightarrow E$  on  $E$  with neutral element  $O$ . By Theorem 4.13, it is necessarily commutative.*

<sup>5</sup>Given a scheme  $X$  and a point  $x \in X$ , we use  $\kappa(x) = \text{Quot}(\mathcal{O}_{X,x}/\mathfrak{m}_x)$  to denote the residue field in  $x$ .

FIGURE 2. The  $\mathbb{R}$ -points of the two Weierstrass equations  $y^2 = x^3 + 1$  and  $y^2 = x^3 - x$ . Note that  $V(y^2 - (x^3 - x)) \subset \mathbb{A}_{\mathbb{R}}^2$  is a connected scheme. Only its  $\mathbb{R}$ -points when endowed with the real topology are disconnected.

There are two approaches to this theorem. Today, we will explain the more elementary one, which is to give a geometric construction of  $+$  in terms of the geometry of  $\mathbb{P}^2$ . A beautiful aspect of this construction is that it brings out clearly why *cubic* curves behave so special. Details on some calculations behind this approach may be found in Silverman's book [15, §III.1-3].

The second approach is based on line bundles, the Riemann–Roch Theorem, and the Yoneda Lemma. It is more conceptual, and some of its aspects will be discussed in more detail later in the course. A reference is [9, §7].

*Sketch of proof of Theorem 5.2.* We will admit the uniqueness part of the theorem, which is a general property of abelian varieties [9, Proposition 3.6]. Thus, the main problem is to construct the addition law.

**Lemma 5.3.** *Let  $F \in k[X, Y, Z]$  be homogeneous of degree 3 without linear factor and let  $E = V_+(F)$ . Let  $L \subset \mathbb{P}_k^2$  be any line. Then  $E$  intersects  $L$  in three points when counted with multiplicities. More precisely,  $E \cap L = \text{Spec } A$  for a  $k$ -algebra  $A$  with  $\dim_k(A) = 3$ .*

Here, by line we mean a curve of the form  $V_+(aX + bY + cZ)$ , where  $(a, b, c) \neq (0, 0, 0)$ .

*Proof.* After a linear change of coordinates, we may assume that  $L = V_+(Z)$ . Since  $F$  has no linear factor,  $Z \nmid F$ . Thus  $F|_L = F(X, Y, 0)$  is a non-zero homogeneous polynomial of degree 3 and hence has three zeroes (counted with multiplicities) as claimed.  $\square$

**Construction 5.4.** Given  $P, Q \in E(k)$ , define a line  $L \subset \mathbb{P}_k^2$  as follows:

- (1) If  $P \neq Q$ , then let  $L$  be the unique line that passes through  $P$  and  $Q$ .
- (2) If  $P = Q$ , then let  $L$  be the tangent line to  $E$  in that point.

The definition of the tangent uses the smoothness of  $E$ . (In a local chart, take the line perpendicular to the gradient of the equation defining  $E$ .) The smoothness of  $E$  also implies that  $F$  has no linear factor. Hence Lemma 5.3 applies and shows that  $E$  and  $L$  intersect in three points (counting multiplicities). But two of these points are known to be  $P$  and  $Q$  which lie in  $L(k)$ ! And if a cubic polynomial has two rational roots, then the third root is rational as well. Thus there exists a unique third rational intersection point  $R \in (E \cap L)(k)$ . Repeating this construction with  $O, R$  instead of  $P, Q$ , defines a fourth point  $S \in E(k)$ .

**Definition 5.5.** The sum of  $P, Q \in E(k)$  is defined as  $P + Q := S$ .

It is true, but not obvious, that this defines a group structure on  $E(k)$ . The fun and easy part is to show that  $O$  is a neutral element and that every element has an inverse

FIGURE 3. The case  $P \neq Q$  is shown on the left, the tangent construction when  $P = Q$  on the right. The point  $O$  here is the point  $[0 : 1 : 0]$  at infinity. The vertical dotted lines are the lines through  $O$  and  $R$ . The picture is taken from [15, §III].

(exercise). It is moreover clear that the operation  $(P, Q) \mapsto P + Q$  is commutative. Showing associativity is more tricky, however.

So far, we have defined a commutative group  $E(k)$ . If  $K/k$  is a field extension, then we can apply the above construction to  $K \otimes_k E \subset \mathbb{P}_K^2$  and obtain a group structure on  $E(K) = (K \otimes_k E)(K)$ . We know from algebraic geometry that, given reduced varieties (smooth, for example)  $X$  and  $Y$  over an algebraically closed field  $K$ , then a morphism  $f : X \rightarrow Y$  is uniquely determined by the map  $f(K) : X(K) \rightarrow Y(K)$  on  $K$ -points. So there is at most one morphism  $E \times_{\text{Spec}(k)} E \rightarrow E$  that induces the above group structures on all the  $E(K)$ ,  $K/k$ . Moreover, if it exists, it will satisfy all group axioms because the sets  $E(K)$  do (apply the uniqueness to the diagrams (4.3) and (4.4)).

To complete the proof, one carries out Construction 5.4 in indeterminates and sees that it indeed comes from a morphism of varieties. We refer the curious reader to [15, Theorem 3.6].  $\square$

**5.2. Elliptic curves have genus 1.** We have just discussed how to upgrade a cubic curve with rational point in  $\mathbb{P}_k^2$  to an elliptic curve. The next important result states that this construction, in fact, provides *all* elliptic curves over  $k$ . In order to prove this, we need to find a way to extract geometric properties of  $E$  (embedding as a cubic into  $\mathbb{P}_k^2$ ) from the existence of the group structure. This is done using differential forms. Let us begin by recalling their definition.

**Definition 5.6.** Let  $R$  be a ring,  $A$  an  $R$ -algebra, and  $M$  an  $A$ -module. An  $R$ -derivation from  $A$  to  $M$  is an  $R$ -linear map  $\delta : A \rightarrow M$  such that the Leibniz rule holds: For all  $a, b \in A$ ,

$$\delta(ab) = a\delta(b) + b\delta(a).$$

**Lemma 5.7.** *There exists a universal  $R$ -derivation. That is, there exists an  $A$ -module  $\Omega_{A/R}^1$  together with an  $R$ -derivation  $d : A \rightarrow \Omega_{A/R}^1$  such that every  $R$ -derivation  $\delta : A \rightarrow M$  factors through a unique  $A$ -module homomorphism  $\varphi : \Omega_{A/R}^1 \rightarrow M$ . As diagram,*

$$\begin{array}{ccc} A & \xrightarrow{d} & \Omega_{A/R}^1 \\ & \searrow \forall \delta & \downarrow \exists! \varphi \\ & & M. \end{array} \quad (5.5)$$

The pair  $(\Omega_{A/R}^1, d)$  is called the module of Kähler differentials of  $A$  over  $R$ . It is easy to describe in terms of generators and relations. Let

$$A = R[X_1, \dots, X_n]/(f_1, \dots, f_m)$$

be a presentation of  $A$  as a quotient of a polynomial ring over  $R$ . Consider the free module  $\bigoplus_{i=1}^n A dX_i$  generated by symbols  $dX_1, \dots, dX_n$ . (This is really  $A^n$ ; the symbols  $dX_i$  are just the traditional notation for the standard basis here.) For each  $f \in R[X_1, \dots, X_m]$ , we can take the gradient vector

$$df := \frac{\partial f}{\partial X_1} \cdot dX_1 + \dots + \frac{\partial f}{\partial X_n} \cdot dX_n. \quad (5.6)$$

Then

$$\begin{aligned} (A dX_1 \oplus \dots \oplus A dX_n) / \langle df_1, \dots, df_m \rangle &\xrightarrow{\sim} \Omega_{A/R}^1 \\ dX_i &\xrightarrow{\sim} d(X_i). \end{aligned} \quad (5.7)$$

The key ideas for proving Lemma 5.7 and (5.7) are as follows:

- Since  $d : A \rightarrow \Omega_{A/R}^1$  is supposed to be universal, the module  $\Omega_{A/R}^1$  has to be generated by all derivatives  $d(a)$  as  $A$ -module.
- Since every element of  $A$  is a polynomial in the  $X_i$  with  $R$ -coefficients, the Leibniz rule allows to write every  $d(a)$  as an  $A$ -linear combination of the  $d(X_i)$ . Hence, the  $d(X_i)$  already  $\Omega_{A/R}^1$  as  $A$ -module.
- Since the  $f_j \in A$  are zero, also the  $d(f_j)$  in  $\Omega_{A/R}^1$  have to be zero. By the Leibniz rule,

$$d(f_j) = (\partial f / \partial X_1) \cdot d(X_1) + \dots + (\partial f / \partial X_n) \cdot d(X_n),$$

which explains the relations  $df_1, \dots, df_m$  in (5.7).

Given an element  $g \in A$ , there is an isomorphism of  $A[g^{-1}]$ -modules

$$\Omega_{A/R}^1[g^{-1}] \xrightarrow{\sim} \Omega_{A[g^{-1}]/R}^1 \quad (5.8)$$

which is uniquely characterized by sending  $d(a)$  to  $d(a)$ . In other words, the formation of  $\Omega_{A/R}^1$  is compatible with localizations. This means that the construction can be glued from rings to schemes.

**Definition 5.8.** Let  $\pi : X \rightarrow S$  be a morphism of schemes. The quasi-coherent module with derivation  $d : \mathcal{O}_X \rightarrow \Omega_{X/S}^1$  is defined as the unique datum (up to isomorphism) that is, locally on affine charts  $\text{Spec}(R) \subseteq S$  and  $\text{Spec}(A) \subseteq \pi^{-1}(\text{Spec}(R))$ , given by  $d : A \rightarrow \Omega_{A/R}^1$  glued along (5.8).

The next result gives a characterization of smoothness in terms of Kähler differentials.

**Theorem 5.9.** *Let  $\pi : X \rightarrow S$  be a morphism that is locally of finite presentation with purely  $d$ -dimensional fibers. Then  $\pi$  is smooth if and only if  $\Omega_{X/S}^1$  is locally free of rank  $d$  as  $\mathcal{O}_X$ -module.*

**Definition 5.10** (Genus of a curve). Let  $C \rightarrow \text{Spec}(k)$  be a proper, smooth, geometrically connected curve. By Theorem 5.9,  $\Omega_{C/k}^1$  is a line bundle on  $C$ . Being a coherent sheaf on a proper variety, the space of global sections  $\Omega_{C/k}^1(C)$  is a finite-dimensional  $k$ -vector space. Its dimension is called the genus of  $C$ .

Here, recall that a finite type  $k$ -scheme  $X$  is said to be geometrically reduced, connected, integral, etc. if the base change  $\bar{k} \otimes_k X$  is reduced, connected, integral, etc. An equivalent condition is that for all field extensions  $K/k$ , the base change  $K \otimes_k X$  has the relevant property.

For example, elliptic curves are geometrically connected because they are connected over  $k$  (by definition) and have a rational point (the neutral element).

**Theorem 5.11.** *Let  $E$  be an elliptic curve over a field  $k$ . Then  $E$  has genus 1.*

*Sketch of proof.* The key point is that the sheaf of differential forms of a group scheme is generated by invariant forms. The proof of this (see [9, Proposition 5.7]) does not concern us here, we will only state and use the result.

Let  $\pi : G \rightarrow S$  be a group scheme with neutral element section  $e : S \rightarrow G$ . Recall that quasi-coherent modules can be pulled back under scheme morphisms. So we may first form  $e^*(\Omega_{G/S}^1)$ , a quasi-coherent  $S$ -module. Then we may again pull back along  $\pi$ . The statement is that there exists an isomorphism

$$\gamma : \pi^* e^* \Omega_{G/S}^1 \xrightarrow{\sim} \Omega_{G/S}^1. \quad (5.9)$$

We now apply (5.9) to our elliptic curve  $E \rightarrow \operatorname{Spec}(k)$ . The pullback  $V = e^*(\Omega_{E/k}^1)$  is a one-dimensional  $k$ -vector space because  $\Omega_{E/k}^1$  is a line bundle. Then (5.9) states that

$$\gamma : \mathcal{O}_E \otimes_k V \xrightarrow{\sim} \Omega_{E/k}^1.$$

Choosing a basis vector  $\omega \in V$ , we have thus obtained an isomorphism  $\mathcal{O}_E \xrightarrow{\sim} \Omega_{E/k}^1$ . The genus of  $E$  is hence  $\dim_k \mathcal{O}_E(E)$ .

**Lemma 5.12.** *Let  $X \rightarrow \operatorname{Spec}(k)$  be a proper  $k$ -scheme that is geometrically reduced and geometrically connected. Then  $\dim_k \mathcal{O}_X(X) = 1$ .*

*Proof.* The global sections  $A = \mathcal{O}_X(X)$  are a finite-dimensional  $k$ -algebra. Its formation commutes with base change in the sense that for every field extension  $K/k$ , we have

$$K \otimes_k A = \mathcal{O}_{K \otimes_k X}(K \otimes_k X).$$

Hence, if  $X$  is geometrically reduced and connected, then  $\bar{k} \otimes_k A$  is reduced and has a unique maximal ideal. The residue field is necessarily  $\bar{k}$  because  $\bar{k}$  is algebraically closed. So  $\bar{k} \xrightarrow{\sim} \bar{k} \otimes_k A$ . Thus  $A$  was one-dimensional to begin with, meaning  $k \xrightarrow{\sim} A$ .  $\square$

Coming back to our elliptic curve  $E \rightarrow \operatorname{Spec}(k)$ , we see that  $\mathcal{O}_E(E) = k$ , meaning that  $E$  has genus 1 as claimed.  $\square$

**5.3. Genus 1 curves as cubics.** We have just shown that every elliptic curve has genus 1. In order to complete the circle of equivalent definitions (a triangle, actually), it is left to realize curves of genus 1 as cubic curves in  $\mathbb{P}^2$ . Let us first briefly recall a bit of general formalism.

**Construction 5.13.** Let  $X$  be a  $k$ -scheme. Giving a morphism  $f : X \rightarrow \mathbb{P}_k^n$  is the same as giving a line bundle  $\mathcal{L}$  on  $X$  and a surjection of  $\mathcal{O}_X$ -modules

$$\ell : \mathcal{O}_X^{\oplus(n+1)} \twoheadrightarrow \mathcal{L}.$$

Namely, on  $\mathbb{P}_k^n$ , we have the standard line bundle  $\mathcal{O}(1)$ . It is generated by the  $n+1$  global sections  $X_0, \dots, X_n$  corresponding to the  $n+1$  coordinates on  $\mathbb{P}_k^n$ . That is, we have a surjection

$$\mathcal{O}_{\mathbb{P}_k^n}^{\oplus(n+1)} \twoheadrightarrow \mathcal{O}(1), \quad e_i \mapsto X_i.$$

Given  $f : X \rightarrow \mathbb{P}_k^n$ , we can pull back that surjection and obtain a pair  $\mathcal{L} = f^*\mathcal{O}(1)$ ,  $\ell : \mathcal{O}_X^{\oplus(n+1)} \twoheadrightarrow \mathcal{L}$  as desired.

Conversely, assume that  $(\mathcal{L}, \ell)$  is given and that  $x \in X$  is a point. Let  $U$  be an open neighborhood of  $x$  and  $s \in \mathcal{L}(U)$  such that  $\mathcal{L} = \mathcal{O}_U \cdot s$ . That is, we choose a trivialization of  $\mathcal{L}$  near  $x$ . Then we can write

$$\ell|_U(e_i) = f_i \cdot s$$

for functions  $f_0, \dots, f_n \in \mathcal{O}_X(U)$ . Since  $\ell$  is a surjection, in every point  $y \in U$  at least one of the  $f_i$  is invertible. That is, the expression

$$[f_0 : f_1 : \dots : f_n] : U \longrightarrow \mathbb{P}_k^n$$

makes sense as a morphism given in projective coordinates. It is independent of the choice of  $s$  because  $[\lambda f_0 : \dots : \lambda f_n] = [f_0 : \dots : f_n]$  for every unit  $\lambda \in \mathcal{O}_U(U)^\times$ . So the construction glues to a morphism from all of  $X$ . Denoting by  $s_i = \ell(e_i) \in \mathcal{L}(X)$  the  $i$ -th global section defined by  $\ell$ , this morphism is aptly denote by

$$[s_0 : \dots : s_n] : X \longrightarrow \mathbb{P}_k^n.$$

**Example 5.14.** We know that every line bundle on  $\mathbb{P}_k^1$  is isomorphic to one of the line bundles  $\mathcal{O}(d)$ . The integer  $d \in \mathbb{Z}$  is its degree. We know that

$$\dim_k(\mathcal{O}(d)(\mathbb{P}_k^1)) = \begin{cases} d+1 & \text{if } d \geq 0 \\ 0 & \text{if } d < 0. \end{cases}$$

If  $d \geq 0$ , then a basis for the global sections  $\mathcal{O}(d)(\mathbb{P}^1)$  is given by the monomials

$$X_0^d, X_0^{d-1}X_1, \dots, X_0X_1^{d-1}, X_1^d$$

where  $X_0$  and  $X_1$  are the coordinates on  $\mathbb{P}^1$ . If  $d \geq 0$ , then these monomials also generate  $\mathcal{O}(d)$  as line bundle. That is, the map

$$\mathcal{O}_{\mathbb{P}_k^1}^{\oplus(d+1)} \longrightarrow \mathcal{O}(d), \quad e_i \longmapsto X_0^{d-i}X_1^i$$

is a surjection of quasi-coherent  $\mathcal{O}_{\mathbb{P}_k^1}$ -modules. The corresponding morphism  $\mathbb{P}_k^1 \rightarrow \mathbb{P}_k^d$  is called the Veronese map. It is a closed immersion when  $d \geq 1$ .

What about curves  $C$  other than  $\mathbb{P}_k^1$ ? In this case, there is no explicit classification of line bundles in general. However, there is still a close relation between the genus  $g$  of  $C$ , the degree  $\deg(\mathcal{L})$  of  $\mathcal{L}$ , and the  $k$ -dimension of the global sections  $\mathcal{L}(C)$ .

**Theorem 5.15** (Riemann–Roch). *Let  $C$  be a proper smooth geometrically connected curve of genus  $g$  over a field  $k$ . Then, for every line bundle  $\mathcal{L}$  on  $C$ ,*

$$\dim \mathcal{L}(C) = \deg(\mathcal{L}) + 1 - g + \dim(\Omega_{C/k}^1 \otimes \mathcal{L}^{-1})(C). \quad (5.10)$$

**Corollary 5.16.** *The degree of  $\Omega_{C/k}^1$  is  $2g - 2$ .*

*Proof.* Apply Theorem 5.15 to  $\Omega_{C/k}^1$ . We obtain

$$g = \deg(\Omega_{C/k}^1) + 1 - g + 1$$

which we may rearrange as claimed.  $\square$

**Corollary 5.17.** *Let  $C/k$  be a proper smooth geometrically connected curve of genus 1 and let  $\mathcal{L}$  be a line bundle of degree  $\deg(\mathcal{L}) \geq 1$  on  $C$ . Then*

$$\dim \mathcal{L}(C) = \deg(\mathcal{L}).$$

*Proof.* By Corollary 5.16,  $\deg(\Omega_{C/k}^1) = 0$ . Since  $\deg(\mathcal{L}) \geq 1$ , we then have

$$\deg(\Omega_{C/k}^1 \otimes \mathcal{L}^{-1}) = 0 - \deg(\mathcal{L}) < 0.$$

Line bundles of negative degree cannot have non-zero global sections, so  $(\Omega_{C/k}^1 \otimes \mathcal{L}^{-1})(C) = 0$ . Evaluating (5.10), we find  $\dim \mathcal{L}(C) = \deg(\mathcal{L})$  as claimed.  $\square$

**Theorem 5.18.** *Let  $E$  be a proper, smooth, connected curve over  $k$  such that  $E(k) \neq \emptyset$ . Then there exists a closed immersion  $E \hookrightarrow \mathbb{P}_k^2$  which identifies  $E$  with the curve  $V_+(F)$  defined by a cubic homogeneous polynomial.*

*Proof. Step 1: Construction of a morphism  $E \rightarrow \mathbb{P}_k^2$ .* We have seen in Construction 5.13 that, in order to define a morphism  $E \rightarrow \mathbb{P}_k^2$ , our task is to find a line bundle  $\mathcal{L}$  on  $E$  together with a surjection  $\ell : \mathcal{O}_E^3 \twoheadrightarrow \mathcal{L}$ .

We now draw inspiration from the example of  $\mathbb{P}_k^1$  above. By assumption, there exists a  $k$ -rational point  $x \in E(k)$ . So we have the degree 1 line bundle  $\mathcal{O}_E([x])$ . Let us briefly recall its definition:

We can view  $\{x\} \subset E$  as a closed subscheme of  $E$  that is isomorphic to  $\text{Spec}(k)$ . It is defined by an ideal sheaf  $\mathcal{I}_x \subset \mathcal{O}_E$ . Since  $E$  is smooth and 1-dimensional, the local ring  $\mathcal{O}_{X,x}$  is a discrete valuation ring. Hence  $\mathcal{I}_x$  is locally free of rank 1. Now we define  $\mathcal{O}_E([x])$  as the dual  $\mathcal{I}_x^{-1} = \mathcal{H}om(\mathcal{I}_x, \mathcal{O}_E)$ .

Set  $\mathcal{M} = \mathcal{O}_E([e])$ . The degree of  $\mathcal{M}^{\otimes d}$  is  $d$ .<sup>6</sup> By Corollary 5.17, this means

$$\dim \mathcal{M}^{\otimes d}(E) = d, \quad d \geq 1.$$

We are mostly interested in  $\mathcal{L} = \mathcal{M}^{\otimes 3}$ . For every closed point  $y \in E$  we have an ideal sheaf  $\mathcal{I}_y$  as before. Its degree is  $-\deg(\kappa(y) : k)$ , the negative of the residue field extension degree. On the one hand, by Riemann–Roch, the dimension of global sections strictly decreases when tensoring with  $\mathcal{I}_y$  because the degree goes down:

$$\dim(\mathcal{L} \otimes \mathcal{I}_y)(E) < 3.$$

On the other hand,

$$(\mathcal{L} \otimes \mathcal{I}_y)(E) \subseteq \mathcal{L}(E)$$

are precisely those global sections that vanish in  $y$ .

We conclude that for every closed point  $y \in E$ , there exists a global section  $s \in \mathcal{L}(E)$  that vanishes in  $y$ . This means that  $\mathcal{L}$  is generated by its global sections. That is, after choosing a basis for the three-dimensional vector space  $\mathcal{L}(E)$ , we obtain a surjection

$$\ell : \mathcal{O}_E^{\oplus 3} \twoheadrightarrow \mathcal{L},$$

and hence a morphism  $f : E \rightarrow \mathbb{P}_k^2$  as in Construction 5.13.

*Step 2:  $f$  is a closed immersion.* We can prove that  $f$  is a closed immersion after base change to  $\bar{k}$ . So from now on, we assume that  $k$  is algebraically closed. This helps, because now every closed point  $y \in E$  is  $k$ -rational and, in particular,  $\deg(\mathcal{I}_y) = -1$ . Let  $y, y' \in E$  be two (possibly equal) closed points. Corollary 5.17 implies that

$$\begin{aligned} \dim(\mathcal{L} \otimes \mathcal{I}_y)(E) &= 2 \\ \dim(\mathcal{L} \otimes \mathcal{I}_y \otimes \mathcal{I}_{y'})(E) &= 1. \end{aligned}$$

So, after applying a linear change of coordinates on  $\mathbb{P}_k^2$ , we may assume that our basis  $s_0, s_1, s_2 \in \mathcal{L}(E)$  is chosen with

$$\begin{aligned} s_0 &\in \mathcal{L}(E) \setminus (\mathcal{L} \otimes \mathcal{I}_y)(E), \\ s_1 &\in (\mathcal{L} \otimes \mathcal{I}_y)(E) \setminus (\mathcal{L} \otimes \mathcal{I}_y \otimes \mathcal{I}_{y'})(E). \end{aligned}$$

If  $y \neq y'$ , then this means that

$$[s_0(y) : s_1(y) : s_2(y)] \neq [s_0(y') : s_1(y') : s_2(y')]$$

because  $s_1$  vanishes in  $y$  while it does not vanish in  $y'$ . We conclude that  $f$  is injective at the level of topological spaces. Since  $f$  is also closed by the properness of  $E$ , it is topologically a closed immersion.

Finally, if  $y = y'$ , then the above choice of  $s_1$  ensures that it vanishes to first order in  $y$ , but not to second order. Translating this to local coordinates, one obtains that  $[s_0 : s_1 : s_2]$  is injective on the tangent space  $(\mathfrak{m}_y/\mathfrak{m}_y^2)^\vee$  in  $y$ , which means that  $f$  is even schematically a closed immersion near  $y$ .

*Step 3: Its image is defined by a cubic equation.* □

---

<sup>6</sup>All tensor products during the proof are taken over  $\mathcal{O}_E$ .
